Copyright This document has been placed in the public domain.

PyArmor is a command line tool used to obfuscate python scripts, bind obfuscated scripts to fixed machine or expire obfuscated scripts. It protects Python scripts by the following ways:

- Obfuscate code object to protect constants and literal strings.
- Obfuscate co_code of each function (code object) in runtime.
- Clear f_locals of frame as soon as code object completed execution.
- Verify the license file of obfuscated scripts while running it.

PyArmor supports Python 2.6, 2.7 and Python 3.

PyArmor is tested against Windows, Mac OS X, and Linux.

PyArmor has been used successfully with FreeBSD and embedded platform such as Raspberry Pi, Banana Pi, Orange Pi, TS-4600 / TS-7600 etc. but is not fullly tested against them.

Contents:

2 Contents

CHAPTER 1

Installation

PyArmor is a normal Python package. You can download the archive from PyPi, but it is easier to install using pip where is available, for example:

```
pip install pyarmor
```

or upgrade to a newer version:

```
pip install --upgrade pyarmor
```

There is also web ui for pyarmor, install it by this command:

```
pip install pyarmor-webui
```

1.1 Verifying the installation

On all platforms, the command pyarmor should now exist on the execution path. To verify this, enter the command:

```
pyarmor --version
```

The result should show PyArmor Version X.Y.Z or PyArmor Trial Version X.Y.Z.

If the command is not found, make sure the execution path includes the proper directory.

1.2 Installed commands

The complete installation places these commands on the execution path:

- pyarmor is the main command. See *Using PyArmor*.
- pyarmor-webui is used to open web ui of PyArmor.

If you do not perform a complete installation (installing via pip), these commands will not be installed as commands. However, you can still execute all the functions documented below by running Python scripts found in the distribution folder. The equivalent of the pyarmor command is pyarmor-folder/pyarmor.py.

pyarmor-webui is pyarmor-folder/webui/server.py.

1.3 Clean uninstallation

The following files are created by *pyarmor* after it has been installed:

```
~/.pyarmor/.pyarmor_capsule.zip (since v6.2.0)
~/.pyarmor/license.lic (since v5.8.0)
~/.pyarmor/platforms/

{pyarmor-folder}/license.lic (before v5.8.0)
~/.pyarmor_capsule.zip (before v6.2.0)
```

Run the following commands to make a clean uninstallation:

```
pip uninstall pyarmor

rm -rf ~/.pyarmor
rm -rf {pyarmor-folder} (before v5.8.0)
rm -rf ~/.pyarmor_capsule.zip (before v6.2.0)
```

CHAPTER 2

Using PyArmor

The syntax of the pyarmor command is:

```
pyarmor [command] [options]
```

2.1 Obfuscating Python Scripts

Use command *obfuscate* to obfuscate python scripts. In the most simple case, set the current directory to the location of your program myscript.py and execute:

```
pyarmor obfuscate myscript.py
```

PyArmor obfuscates myscript.py and all the *.py in the same folder:

- Create .pyarmor_capsule.zip in the HOME folder if it doesn't exists.
- Creates a folder dist in the same folder as the script if it does not exist.
- Writes the obfuscated myscript.py in the dist folder.
- Writes all the obfuscated *.py in the same folder as the script in the dist folder.
- Copy runtime files used to run obfuscated scripts to the dist folder.

In the dist folder the obfuscated scripts and all the required files are generated:

```
dist/
   myscript.py

pytransform/
   __init__.py
   __pytransform.so, or _pytransform.dll in Windows, _pytransform.dylib in MacOS
   pytransform.key
   license.lic
```

The extra folder pytransform called *Runtime Package*, it's required to run the obfuscated script.

Normally you name one script on the command line. It's entry script. The content of myscript.py would be like this:

```
from pytransform import pyarmor_runtime
pyarmor_runtime()
__pyarmor__(__name__, __file__, b'\x06\x0f...')
```

The first 2 lines called *Bootstrap Code*, are only in the entry script. They must be run before using any obfuscated file. For all the other obfuscated *.py, there is only last line:

```
__pyarmor__(__name__, __file__, b'\x0a\x02...')
```

Run the obfuscated script:

```
cd dist python myscript.py
```

By default, only the \star .py in the same path as the entry script are obfuscated. To obfuscate all the \star .py in the sub-folder recursively, execute this command:

```
pyarmor obfuscate --recursive myscript.py
```

2.2 Distributing Obfuscated Scripts

Just copy all the files in the output path *dist* to end users. Note that except the obfuscated scripts, the *Runtime Package* need to be distributed to end users too.

The *Runtime Package* may not with the obfuscated scripts, it could be moved to any Python path, only if *import* pytransform works.

About the security of obfuscated scripts, refer to *The Security of PyArmor*

Note: PyArmor need NOT be installed in the runtime machine

2.3 Generating License For Obfuscated Scripts

Use command *licenses* to generate new license.lic for obfuscated scripts.

By default there is dist/pytransform/license.lic generated by command *obfuscate*. It allows obfuscated scripts run in any machine and never expired.

Generate an expired license for obfuscated script:

```
pyarmor licenses --expired 2019-01-01 product-001
```

PyArmor generates new license file:

- Read data from .pyarmor_capsule.zip in the HOME folder
- Create license.lic in the licenses/product-001 folder
- Create license.lic.txt in the licenses/product-001 folder

Overwrite default license with new one:

```
cp licenses/code-001/license.lic dist/pytransform/
```

Run obfuscated script with new license, It will report error after Jan. 1, 2019:

```
cd dist python myscript.py
```

Generate license to bind obfuscated scripts to fixed machine, first get hardware information:

```
pyarmor hdinfo
```

Then generate new license bind to harddisk serial number and mac address:

```
pyarmor licenses --bind-disk "100304PBN2081SF3NJ5T" --bind-mac "20:c1:d2:2f:a0:96" → code-002
```

Run obfuscated script with new license:

```
cp licenses/code-002/license.lic dist/pytransform/
cd dist/
python myscript.py
```

Note: Before v5.7.0, the default license.lic locates in the path dist other than dist/pytransform

2.4 Extending License Type

It's easy to extend any other licese type for obfuscated scripts: **just add authentication code in the entry script**. The script can't be changed any more after it is obfuscated, so do whatever you want in your script. In this case the *Runtime Module pytransform* would be useful.

The prefer way is *Using Plugin to Extend License Type*. The advantage is that your scripts needn't be changed at all. Just write authentication code in a separated script, and inject it in the obfuscated scripts as obfuscating. For more information, refer to *How to Deal With Plugins*

Here are some plugin examples

https://github.com/dashingsoft/pyarmor/tree/master/plugins

2.5 Obfuscating Single Module

To obfuscate one module exactly, use option --exact:

```
pyarmor obfuscate --exact foo.py
```

Only foo.py is obfuscated, now import this obfuscated module:

```
cd dist python -c "import foo"
```

2.6 Obfuscating Whole Package

Run the following command to obfuscate a package:

```
pyarmor obfuscate --recursive --output dist/mypkg mykpg/__init__.py
```

To import the obfuscated package:

```
cd dist
python -c "import mypkg"
```

2.7 Packing Obfuscated Scripts

Use command pack to pack obfuscated scripts into the bundle.

First install *PyInstaller*:

```
pip install pyinstaller
```

Set the current directory to the location of your program myscript.py and execute:

```
pyarmor pack myscript.py
```

PyArmor packs myscript.py:

- Execute pyarmor obfuscate to obfuscate myscript.py
- Execute pyinstaller myscipt.py to create myscript.spec
- Update myscript.spec, replace original scripts with obfuscated ones
- Execute pyinstaller myscript.spec to bundle the obfuscated scripts

In the dist/myscript folder you find the bundled app you distribute to your users.

Run the final executeable file:

```
dist/myscript/myscript
```

Check the scripts have been obfuscated. It should return error:

```
rm dist/myscript/license.lic
dist/myscript/myscript
```

Generate an expired license for the bundle:

```
pyarmor licenses --expired 2019-01-01 code-003
cp licenses/code-003/license.lic dist/myscript
dist/myscript/myscript
```

For complicated cases, refer to command pack and How To Pack Obfuscated Scripts.

2.8 Improving Security Further

These PyArmor features could import security further:

- 1. Using Super Mode to obufscate scripts if possible, otherwise enable Advanced Mode if the platform is supported
- 2. Try to Binding obfuscated scripts to Python interpreter. Generally it's not required for Super Mode.
- 3. Make sure the entry script is patched by cross protection code, and try to Customizing cross protection code
- 4. Use the corresponding *Restrict Mode*
- 5. Use the high security code obfuscation *-obf-code=2*
- 6. Using Plugin To Improve Security by injecting your private checkpoints in the obfuscated scripts

About the security of obfuscated scripts, refer to The Security of PyArmor

CHAPTER 3

Advanced Topics

3.1 Using Super Mode

The *Super Mode* is introduced since v6.2.0, there is only one extension module required to run the obfuscated scripts, and the *Bootstrap Code* which may confused some users before is gone now, all the obfuscated scripts are same. It improves the security remarkably, and makes the usage simple. The only problem is that only the latest Python versions 2.7, 3.7 and 3.8 are supported.

Enable super mode by option --advanced 2, for example:

```
pyarmor obfuscate --advanced 2 foo.py
```

When distributing the obfuscated scripts to any other machine, so long as extension module pytransform in any Python path, the obfuscated scrips could work well.

In order to restirct the obfuscated scripts, generate a license.lic in advanced. For example:

```
pyarmor licenses --bind-mac xx:xx:xx regcode-01
```

Then specify this license with option --with-license, for example:

By this way the specified license file will be embedded into the extension module pytransform. If you prefer to use outer license.lic, so it can be replaced with the others easily, just set option —with—license to special value outer, for example:

```
pyarmor obfuscate --with-license outer --advanced 2 foo.py
```

When the obfuscated scripts start, it will search license.lic in order:

- 1. Check environment variable PYARMOR_LICENSE, if set, use this filename
- 2. If it's not set, search license.lic in the current path

- 3. If not found, search the path of extension module pytransform
- 4. Raise exception if there is still not found

3.2 Obfuscating Many Packages

There are 3 packages: pkg1, pkg2, pkg2. All of them will be obfuscated, and use shared runtime files.

First change to work path, create 3 projects:

```
mkdir build
cd build

pyarmor init --src /path/to/pkg1 --entry __init__.py pkg1

pyarmor init --src /path/to/pkg2 --entry __init__.py pkg2

pyarmor init --src /path/to/pkg3 --entry __init__.py pkg3
```

Then make the *Runtime Package*, save it in the path *dist*:

```
pyarmor build --output dist --only-runtime pkg1
```

Next obfuscate 3 packages, save them in the dist:

```
pyarmor build --output dist --no-runtime pkg1
pyarmor build --output dist --no-runtime pkg2
pyarmor build --output dist --no-runtime pkg3
```

Check all the output and test these obfuscated packages:

```
ls dist/
cd dist
python -c 'import pkg1
import pkg2
import pkg3'
```

Note: The runtime package pytransform in the output path *dist* also could be move to any other Python path, only if it could be imported.

From v5.7.2, the *Runtime Package* also could be generate by command *runtime* separately:

```
pyarmor runtime
```

3.3 Solve Conflicts With Other Obfuscated Libraries

```
Note: New in v5.8.7
```

Suppose there are 2 packages obfuscated by different developers, could they be imported in the same Python interpreter?

If both of them are obfuscated by trial version of pyarmor, no problem, the answer is yes. But if anyone is obfuscated by registerred version, the answer is no.

Since v5.8.7, the scripts could be obfuscated with option —enable—suffix to generate the *Runtime Package* with an unique suffix, other than fixed name pytransform. For example:

```
pyarmor obfuscate --enable-suffix foo.py
```

The output would be like this:

```
dist/
foo.py
pytransform_vax_000001/
__init__.py
...
```

The suffix _vax_000001 is based on the registration code of PyArmor.

For project, set enable-suffix by command *config*:

```
pyarmor config --enable-suffix 1 pyarmor build -B
```

Or disable it by this way:

```
pyarmor config --enable-suffix 0 pyarmor build -B
```

3.4 Distributing Obfuscated Scripts To Other Platform

First list all the avaliable platform names by command *download*:

```
pyarmor download pyarmor download --help-platform
```

Display the detials with option --list:

```
pyarmor download --list
pyarmor download --list windows
pyarmor download --list windows.x86_64
```

Then specify platform name when obfuscating the scripts:

```
pyarmor obfuscate --platform linux.armv7 foo.py
# For project
pyarmor build --platform linux.armv7
```

3.4.1 Obfuscating scripts with different features

There may be many available dynamic libraries for one same platform. Each one has different features. For example, both of windows.x86_64.0 and windows.x86_64.7 work in the platform windwos.x86_64. The last number stands for the features:

• 0: No anti-debug, JIT, advanced mode features, high speed

• 7: Include anti-debug, JIT, advanced mode features, high security

It's possible to obfuscate the scripts with special feature. For example:

```
pyarmor obfuscate --platform linux.x86_64.7 foo.py
```

Note that the dynamic library with different features aren't compatible. For example, try to obfuscate the scripts with --platform linux.arm.0 in Windows:

```
pyarmor obfuscate --platform linux.arm.0 foo.py
```

Because the default platform is full features windows.x86_64.7 in Windows, so PyArmor have to reboot with platform windows.x86_64.0, then obfuscate the script for this low feature platform linux.arm.0.

It also could be set the enviornment variable PYARMOR_PLATFORM to same feature platform as target machine. For example:

```
PYARMOR_PLATFORM=windows.x86_64.0 pyarmor obfuscate --platform linux.arm.0 foo.py

# In Windows
set PYARMOR_PLATFORM=windows.x86_64.0
pyarmor obfuscate --platform linux.arm.0 foo.py
set PYARMOR_PLATFORM=
```

3.4.2 Running Obfuscated Scripts In Multiple Platforms

From v5.7.5, the platform names are standardized, all the available platform names list here *Standard Platform Names*. And the obfuscated scripts could be run in multiple platforms.

In order to support multiple platforms, all the dynamic libraries for these platforms need to be copied to *Runtime Package*. For example, obfuscating a script could run in Windows/Linux/MacOS:

The *Runtime Package* also could be generated by command *runtime* once, then obfuscate the scripts without runtime files. For examples:

Because the obfuscated scripts will check the dynamic library, the platforms must be specified even if there is option —no-runtime. But if the option —no-cross—protection is specified, the obfuscated scripts will not check the dynamic library, so no platform is required. For example:

```
pyarmor obfuscate --no-runtime --recursive --no-cross-protection foo.py
```

Note: If the feature number is specified in one of platform, for example, one is windows.x86_64.0, then all the other platforms must be same feature.

Note: If the obfuscated scripts don't work in other platforms, try to update all the downloaded files:

pyarmor download --update

If it still doesn't work, try to remove the cahced platform files in the path \$HOME/.pyarmor

3.5 Obfuscating Scripts By Other Python Version

If there are multiple Python versions installed in the machine, the command *pyarmor* uses default Python. In case the scripts need to be obfuscated by other Python, run *pyarmor* by this Python explicitly.

For example, first find pyarmor.py:

find /usr/local/lib -name pyarmor.py

Generally it should be in the /usr/local/lib/python2.7/dist-packages/pyarmor in most of linux.

Then run pyarmor as the following way:

/usr/bin/python3.6 /usr/local/lib/python2.7/dist-packages/pyarmor/pyarmor.py

It's convenient to create a shell script /usr/local/bin/pyarmor3, the content is:

/usr/bin/python3.6 /usr/local/lib/python2.7/dist-packages/pyarmor/pyarmor.py "\$@"

And

chmod +x /usr/local/bin/pyarmor3

then use pyarmor3 as before.

In the Windows, create a bat file *pyarmor3.bat*, the content would be like this:

C:\Python36\python C:\Python27\Lib\site-packages\pyarmor\pyarmor.py %*

3.6 Run bootstrap code in plain scripts

Before v5.7.0 the *Bootstrap Code* could be inserted into plain scripts directly, but now, for the sake of security, the *Bootstrap Code* must be in the obfuscated scripts. It need another way to run the *Bootstrap Code* in plain scripts.

First create one bootstrap package pytransform bootstrap by command runtime:

pyarmor runtime -i

Next move bootstrap package to the path of plain script:

mv dist/pytransform_bootstrap /path/to/script

It also could be copied to python system library, for examples:

mv dist/pytransform_bootstrap /usr/lib/python3.5/ (For Linux)
mv dist/pytransform_bootstrap C:/Python35/Lib/ (For Windows)

Then edit the plain script, insert one line:

```
import pytransform bootstrap
```

Now any other obfuscated modules could be imported after this line.

Note: Before v5.8.1, create this bootstrap package by this way:

```
echo "" > __init__.py
pyarmor obfuscate -0 dist/pytransform_bootstrap --exact __init__.py
```

3.6.1 Run unittest of obfuscated scripts

In most of obfuscated scripts there are no *Bootstrap Code*. So the unittest scripts may not work with the obfuscated scripts.

Suppose the test script is /path/to/tests/test_foo.py, first patch this test script, refer to run bootstrap code in plain scripts

After that it works with the obfuscated modules:

```
cd /path/to/tests
python test_foo.py
```

The other way is patch system package unittest directly. Make sure the bootstrap package pytransform_bootstrap is copied in the Python system library, refer to run bootstrap code in plain scripts

Then edit /path/to/unittest/__init__.py, insert one line:

```
import pytransform_bootstrap
```

Now all the unittest scripts could work with the obfuscated scripts. It's useful if there are many unittest scripts.

3.7 Let Python Interpreter Recognize Obfuscated Scripts Automatically

In a few cases, if Python Interpreter could recognize obfuscated scripts automatically, it will make everything simple:

- Almost all the obfuscated scripts will be run as main script
- In the obfuscated scripts call multiprocessing to create new process
- Or call *Popen*, os.exec etc. to run any other obfuscated scripts
- ...

Here are the base steps:

1. First create one bootstrap package pytransform_bootstrap:

```
pyarmor runtime -i
```

Before v5.8.1, it need be created by obfuscating an empty package:

```
echo "" > __init__.py
pyarmor obfuscate -O dist/pytransform_bootstrap --exact __init__.py
```

2. Then create virtual python environment to run the obfuscated scripts, move the bootstrap package to virtual python library. For example:

```
# For windows
mv dist/pytransform_bootstrap venv/Lib/
# For linux
mv dist/pytransform_bootstrap venv/lib/python3.5/
```

4. Edit venv/lib/site.py or venv/lib/pythonX.Y/site.py, import pytransform_bootstrap before the main line:

```
import pytransform_bootstrap
if __name__ == '__main__':
    ...
```

It also could be inserted into the end of function main, or anywhere they could be executed as module site is imported.

After that in the virtual environment python could run the obfuscated scripts directly, because the module site is automatically imported during Python initialization.

Refer to https://docs.python.org/3/library/site.html

Note: The command *pyarmor* doesn't work in this virtual environment, it's only used to run the obfuscated scripts.

Note: Before v5.7.0, you need create the bootstrap package by the *Runtime Files* manually.

3.8 Obfuscating Python Scripts In Different Modes

Advanced Mode is introduced from PyArmor 5.5.0, it's disabled by default. Specify option --advanced to enable it:

```
pyarmor obfuscate --advanced 1 foo.py

# For project
cd /path/to/project
pyarmor config --advanced 1
pyarmor build -B
```

From PyArmor 5.2, the default *Restrict Mode* is 1. It could be changed by the option --restrict:

```
pyarmor obfuscate --restrict=2 foo.py
pyarmor obfuscate --restrict=3 foo.py

# For project
cd /path/to/project
pyarmor config --restrict 4
pyarmor build -B
```

All the restricts could be disabled by this way if required:

```
pyarmor obfuscate --restrict=0 foo.py

# For project
pyarmor config --restrict=0
pyarmor build -B
```

The modes of *Obfuscating Code Mode*, *Wrap Mode*, *Obfuscating module Mode* could not be changed in command obfucate. They only could be changed by command *config* when *Using Project*. For example:

```
pyarmor init --src=src --entry=main.py .
pyarmor config --obf-mod=1 --obf-code=1 --wrap-mode=0
pyarmor build -B
```

3.9 Using Plugin to Extend License Type

PyArmor could extend license type for obfuscated scripts by plugin. For example, check internet time other than local time.

First create plugin script check_ntp_time.py. The key function in this script is *check_ntp_time*, the other important function is _*get_license_data* which used to get extra data from the *license.lic* of obfuscated scripts.

Then insert 2 comments in the entry script foo.py:

```
# {PyArmor Plugins}
# PyArmor Plugin: check_ntp_time()
```

Now obfuscate entry script:

```
pyarmor obfuscate --plugin check_ntp_time foo.py
```

If the plugin file isn't in the current path, use absolute path instead:

```
pyarmor obfuscate --plugin /usr/share/pyarmor/check_ntp_time foo.py
```

Finally generate one license file for this obfuscated script, pass extra license data by option -x, this data could be got by function $_get_license_data$ in the plugin script:

```
pyarmor licenses -x 20190501 rcode-001
cp licenses/rcode-001/license.lic dist/
```

More examples, refer to https://github.com/dashingsoft/pyarmor/tree/master/plugins

About how plugins work, refer to How to Deal With Plugins

Important: The output function name in the plugin must be same as plugin name, otherwise the plugin will not take effects.

3.10 Bundle Obfuscated Scripts To One Executable File

Run the following command to pack the script *foo.py* to one executable file *dist/foo.exe*. Here *foo.py* isn't obfuscated, it will be obfuscated before packing:

```
pyarmor pack -e " --onefile" foo.py
dist/foo.exe
```

If you don't want to bundle the *license.lic* of the obfuscated scripts into the executable file, but put it outside of the executable file. For example:

```
dist/
foo.exe
license.lic
```

So that we could generate different licenses for different users later easily. Here are basic steps:

1. First create runtime-hook script *copy_licese.py*:

```
import sys
from os.path import join, dirname
with open(join(dirname(sys.executable), 'license.lic'), 'rb') as fs:
    with open(join(sys._MEIPASS, 'license.lic'), 'wb') as fd:
        fd.write(fs.read())
```

2. Then pack the scirpt with extra options:

Option —without—license tells *pack* not to bundle the *license.lic* of obfuscated scripts to the final executable file. By option—runtime—hook of PyInstaller, the specified script copy_licesen.py will be executed before any obfuscated scripts are imported. It will copy outer license.lic to right path.

Try to run dist/foo.exe, it should report license error.

3. Finally run *licenses* to generate new license for the obfuscated scripts, and copy new license.lic and dist/foo.exe to end users:

```
pyarmor licenses -e 2020-01-01 code-001
cp license/code-001/license.lic dist/
dist/foo.exe
```

3.11 Bundle obfuscated scripts with customized spec file

If there is a customized .spec file works, for example:

```
pyinstaller myscript.spec
```

It could be used to pack obfuscated scripts directly:

```
pyarmor pack -s myscript.spec myscript.py
```

If it raises this error:

```
Unsupport .spec file, no XXX found
```

Check .spec file, make sure there are 2 lines in top level (no identation):

```
a = Analysis(...
pyz = PYZ(...
```

And there are 3 key parameters when creating an *Analysis* object, for example:

```
a = Analysis(
    ...
    pathex=...,
    hiddenimports=...,
    hookspath=...,
    ...
)
```

PyArmor will append required options to these lines automatically. But before v5.9.6, it need to be patched by manual:

- Add module pytransform to hiddenimports
- Add extra path DISTPATH/obf/temp to pathex and hookspath

After changed, it may be like this:

Note: This featuer is introduced since v5.8.0

Before v5.8.2, the extra path is DISTPATH/obf, not DISTPATH/obf/temp

3.12 Improving The Security By Restrict Mode

By default the scripts are obfuscated by restrict mode 1, that is, the obfuscated scripts can't be changed. In order to improve the security, obfuscating the scripts by restrict mode 2 so that the obfuscated scripts can't be imported out of the obfuscated scripts. For example:

```
pyarmor obfuscate --restrict 2 foo.py
```

Or obfuscating the scripts by restrict mode 3 for more security. It will even check each function call to be sure all the functions are called in the obfuscated scripts. For example:

```
pyarmor obfuscate --restrict 3 foo.py
```

However restrict mode 2 and 3 aren't applied to Python package. There is another solution for Python package to improve the security:

- The .py files which are used by outer scripts are obfuscated by restrice mode 1
- All the other .py files which are used only in the package are obfuscated by restrict mode 4

For example:

More information about restrict mode, refer to Restrict Mode

3.13 Using Plugin To Improve Security

By plugin any private checkpoint could be injected into the obfuscated scripts, and it doesn't impact the original scripts. Most of them must be run in the obfuscated scripts, if they're not commented as plugin, it will break the plain scripts.

No one knows your check logic, and you can change it in anytime. So it's more security.

3.13.1 Using Inline Plugin To Check Dynamic Library

Althouth *PyArmor* provides cross protection, it also could check the dynamic library in the startup to make sure it's not changed by others. This example uses inline plugin to check the modified time protecting the dynamic library by inserting the following comment to main.py

Then obfuscate the script and enable inline plugin by this way:

```
pyarmor obfuscate --plugin on main.py
```

Once the obfuscated script starts, the following plugin code will be run at first

```
import os
libname = os.path.join( os.path.dirname( __file__ ), '_pytransform.so' )
if not os.stat( libname ) .st_mtime_ns == 102839284238:
    raise RuntimeError('Invalid Library')
```

3.13.2 Checking Imported Function Is Obfuscated

Sometimes it need to make sure the imported functions from other module are obfuscated. For example, there are 2 scripts *main.py* and *foo.py*

```
#
# This is main.py
#
import foo

def start_server():
    foo.connect('root', 'root password')
    foo.connect2('user', 'user password')
```

(continues on next page)

(continued from previous page)

```
#
# This is foo.py
#

def connect(username, password):
    mysql.dbconnect(username, password)

def connect2(username, password):
    db2.dbconnect(username, password)
```

In the *main.py*, it need to be sure *foo.connect* is obfuscated. Otherwise the end users may replace the obfuscated *foo.py* with this plain script, and run the obfuscated *main.py*

```
def connect(username, password):
   print('password is %s', password)
```

The password is stolen, in order to avoid this, use decorator function to make sure the function *connect* is obfuscated by plugin.

From v6.0.2, the *Runtime Package* pytransform provides internal decorator *assert_armored*, it can be used to check all the list functions are pyarmored in the script. Now let's edit *main.py*, insert inline plugin code

```
import foo

# PyArmor Plugin: from pytransform import assert_armored

# PyArmor Plugin: @assert_armored(foo.connect, foo.connect2)

def start_server():
    foo.connect('root', 'root password')
```

Then obfuscate it with plugin on:

```
pyarmor obfuscate --plugin on main.py
```

The obfuscated script would be like this

```
import foo

from pytransform import assert_armored

@assert_armored(foo.connect, foo.connect2)
def start_server():
    foo.connect('root', 'root password')
```

Before call start_server, the decorator function assert_armored will check both connect functions are pyarmored, otherwise it will raise exception.

In order to improve security further, we implement the decorator function in the script, instead of importing it. First create script assert_armored.py in the current path

```
from pytransform import _pytransform, PYFUNCTYPE, py_object

def assert_armored(*names):
    prototype = PYFUNCTYPE(py_object, py_object)
    dlfunc = prototype(('assert_armored', _pytransform))
```

(continues on next page)

(continued from previous page)

Next edit main.py, insert plugin markers

```
import foo

# {PyArmor Plugins}

# PyArmor Plugin: @assert_armored(foo.connect, foo.connect2)
def start_server():
    foo.connect('root', 'root password')
```

Then obfuscate it with this command:

```
pyarmor obfuscate --plugin assert_armored main.py
```

Note: Since v6.2.0, if obfuscating scripts by *Super Mode*, it's enough to import *assert_armored* from pytransform, do not create outer script, it doesn't work.

3.14 Call pyarmor From Python Script

It's also possible to call PyArmor methods inside Python script not by os. exec or subprocess. Popen etc. For example

```
from pyarmor.pyarmor import main as call_pyarmor
call_pyarmor(['obfuscate', '--recursive', '--output', 'dist', 'foo.py'])
```

In order to suppress all normal output of pyarmor, call it with --silent

```
from pyarmor.pyarmor import main as call_pyarmor
call_pyarmor(['--silent', 'obfuscate', '--recursive', '--output', 'dist', 'foo.py'])
```

From v5.7.3, when pyarmor called by this way and something is wrong, it will raise exception other than call sys.exit.

3.14.1 Generating license key by web api

It's also possible to generate license key as string other than writing to a file inside Python script. It may be useful in case the new license need to be generated by web api.

If there are more than one product need generate licenses from one Web API, set keyword *home* to each registerred product. For example

3.15 Check license periodly when the obfuscated script is running

Generally only at the startup of the obfuscated scripts the license is checked. Since v5.9.3, it also could check the license per hour. Just generate a new license with --enable-period-mode and overwrite the default one. For example:

```
pyarmor obfuscate foo.py
pyarmor licenses --enable-period-mode code-001
cp licenses/code-001/license.lic ./dist
```

3.16 Work with Nuitka

Because the obfuscated scripts could be taken as normal scripts with an extra runtime package *pytransform*, they also could be translated to C program by Nuitka. When obfuscating the scripts, the option $--restrict\ 0$ and --no-cross-protection should be set, otherwise the final C program could not work. For example, first obfustate the scripts:

```
pyarmor obfuscate --restrict 0 --no-cross-protection foo.py
```

Then translate the obfuscated one as normal python scripts by Nuitka:

```
cd ./dist
python -m nuitka --include-package pytransform foo.py
./foo.bin
```

There is one problem is that the imported modules (packages) in the obfuscated scripts could not be seen by Nuitka. To fix this problem, first generate the corresponding .pyi with original script, then copy it within the obfuscated one. For example:

```
# Generating "mymodule.pyi"
python -m nuitka --module mymodule.py

pyarmor obfuscate --restrict 0 --no-bootstrap mymodule.py
cp mymodule.pyi dist/

cd dist/
python -m nuitka --module mymodule.py
```

But it may not take advantage of Nuitka features by this way, because most of byte codes aren't translated to c code indeed.

Note: So long as the C program generated by Nuitka is linked against libpython to execute, pyarmor could work with Nuitka. But in the future, just as said in the Nuitka official website:

```
It will do this - where possible - without accessing libpython but in C with its native data types.
```

In this case, pyarmor maybe not work with Nuitka.

3.17 Work with Cython

Here it's an example show how to cythonize a python script foo.py obfuscated by pyarmor with Python37:

```
print('Hello Cython')
```

First obfuscate it with some extra options:

```
pyarmor obfuscate --package-runtime 0 --no-cross-protection --restrict 0 foo.py
```

The obfuscated script and runtime files will be saved in the path *dist*, about the meaning of each options, refer to command *obfuscate*.

Next *cythonize* both *foo.py* and *pytransform.py* with extra options -k and --lenient to generate *foo.c* and *pytransform.c*:

```
cd dist
cythonize -3 -k --lenient foo.py pytransform.py
```

Without options -k and --lenient, it will raise exception:

```
undeclared name not builtin: __pyarmor__
```

Then compile foo.c and pytransform.c to the extension modules. In MacOS, just run the following commands, but in Linux, with extra cflag -fPIC:

```
gcc -shared $(python-config --cflags) $(python-config --ldflags) \
    -o foo$(python-config --extension-suffix) foo.c

gcc -shared $(python-config --cflags) $(python-config --ldflags) \
    -o pytransform$(python-config --extension-suffix) pytransform.c
```

Finally test it, remove all the .py files and import the extension modules:

```
mv foo.py pytransform.py /tmp
python -c 'import foo'
```

It will print Hello Cython as expected.

3.18 Work with PyUpdater

PyArmor should work with PyUpdater by this way, for example, there is a script foo.py:

- 1. Generate foo.spec by PyUpdater
- 2. Generate foo-patched.spec by pyarmor with option --debug:

```
pyarmor pack --debug -s foo.spec foo.py

# If the final executable raises protection error, try to disable restirct mode
# by the following extra options
pyarmor pack --debug -s foo.spec -x " --restrict 0 --no-cross-protection" foo.py
```

This patched foo-patched.spec could be used by PyUpdater in build command

If your Python scripts are modified, just obfuscate them again, all the options for command *obfuscate* could be got from the output of command *pack*

If anybody is having issues with the above. Just normally compiling it in PyArmor then zipping and putting it into "/pyu-data/new" works. From there on you can just normally sign, process and upload your update.

More information refer to the description of command *pack* and advanced usage bundle-obfuscated-scripts-with-customized-spec-file

3.19 Binding obfuscated scripts to Python interpreter

In order to improve the security of obfuscated scripts, it also could bind the obfuscated scripts to one fixed Python interperter, the obfuscated scripts will not work if the Python dynamic library are changed.

If you use command *obfuscate*, after the scripts are obfuscated, just generate a new *license.lic* which is bind to the current Python and overwrite the default license. For example:

```
pyarmor licenses --fixed 1 -O dist/license.lic
```

When start the obfuscated scripts in target machine, it will check the Python dynamic library, it may be pythonXY.dll, libpythonXY.so or libpythonXY.dylib in different platforms. If this library is different from the python dynamic library in build machine, the obfuscated script will quit.

If you use project to obfuscate scripts, first generate a fixed license:

```
cd /path/to/project
pyarmor licenses --fixed 1
```

By default it will be saved to *licenses/pyarmor/license.lic*, then configure the project with this license:

```
pyarmor config --license=licenses/pyarmor/license.lic
```

If obfuscate the scripts for different platform, first get the bind key in target platform. Create a script then run it with Python interpreter which would be bind to:

```
from ctypes import CFUNCTYPE, cdll, pythonapi, string_at, c_void_p, c_char_p
from sys import platform
def get_bind_key():
    if platform.startswith('win'):
        from ctypes import windll
        dlsym = windll.kernel32.GetProcAddressA
    else:
        prototype = CFUNCTYPE(c_void_p, c_void_p, c_char_p)
        dlsym = prototype(('dlsym', cdll.LoadLibrary(None)))
    refunc1 = dlsym(pythonapi._handle, b'PyEval_EvalCode')
   refunc2 = dlsym(pythonapi._handle, b'PyEval_GetFrame')
    size = refunc2 - refunc1
   code = string_at(refunc1, size)
   print('Get bind key: %s' % sum(bytearray(code)))
if __name__ == '__main__':
   get_bind_key()
```

It will print the bind key xxxxxx, then generate one fixed license with this bind key:

```
pyarmor licenses --fixed xxxxxx -O dist/license.lic
```

It also could bind the license to many Python interpreters by passing multiple keys separated by ;:

```
pyarmor licenses --fixed 1,key2,key3 -0 dist/license.lic
pyarmor licenses --fixed key1,key2,key3 -0 dist/license.lic
```

The special key 1 means current Python interpreter.

Note: Do not use this feature in 32-bit Windows, because the bind key is different in different machine, it may be changed even if python is restarted in the same machine.

3.20 Customizing cross protection code

In order to protect core dynamic library of PyArmor, the default protection code will be injected into the entry scripts, refer to *Special Handling of Entry Script*. However this public protection code may be bypassed deliberately, the better way is to write your private protection code, it could improve the security largely.

Since v6.2.0, command *runtime* could generate the default protection code, it could be as template to write your own protection code. Of course, you may write it by yourself. Only if it could make sure the runtime files aren't changed by someone else as running the obfuscated scripts.

First generate protection script build/pytransform_protection.py:

```
pyarmor runtime --super-mode --output build
```

Then edit it with your private code, after that, obfuscate the scripts and set option --cross-protection to this customized script, for example:

Note that *Super Mode* is total different from other modes, don't specify option —super—mode when generating runtime files for other modes, for example:

```
pyarmor runtime --output build
```

Note: Obfuscating with --advanced 1 is not super mode, only --advanced 2 is super mode.

3.21 Storing runtime file license.lic to any location

By creating a symbol link in the runtime package, it's easy to store runtime file license.lic to any location when running the obfuscated scripts.

In linux, for example, store license file in /opt/my_app:

```
ln -s /opt/my_app/license.lic /path/to/obfuscated/pytransform/license.lic
```

In windows, store license file in C:/Users/Jondy/my_app:

```
mklink \path\to\obfuscated\pytransform\license.lic C:\Users\Jondy\my_app\license.lic
```

When distributing the obfuscated package, just run this function on post-install:

```
import os

def make_link_to_license_file(package_path, target_license="/opt/mypkg/license.lic"):
    license_file = os.path.join(package_path, 'pytransform', 'license.lic')
    if os.path.exists(license_file):
        os.rename(license_file, target_license)
    os.symlink(target_license, license_file)
```

3.22 Register multiple pyarmor in same machine

From v5.9.0, pyarmor reads license and capsule data from environment variable *PYARMOR_HOME*, the default value is ~/.pyarmor. So it's easy to register multiple pyarmor in one machine by setting environment variable *PYARMOR_HOME* to another path before run pyarmor.

It also could create a new command *pyarmor2* for the second project by the following way.

In Linux, create a shell script pyarmor2

```
export PYARMOR_HOME=$HOME/.pyarmor_2
pyarmor "$0"
```

Save it to /usr/local/pyarmor2, and change its mode:

```
chmod +x /usr/local/pyarmor2
```

In Windows, create a bat script pyarmor2.bat

```
SET PYARMOR_HOME=%HOME%\another_pyarmor pyarmor %*
```

After that, run *pyarmor2* for the second project:

```
pyarmor2 register pyarmor-regkey-2.zip
pyarmor2 obfuscate foo2.py
```

3.23 How to get license information of one obfuscated package

How to get the license information of one obfuscated package? Since v6.2.5, just run this script in the path of runtime package pytransform

```
from pytransform import pyarmor_init, get_license_info
pyarmor_init(is_runtime=1)
licinfo = get_license_info()
print('This obfuscated package is issued by %s' % licinfo['ISSUER'])
print('License information:')
print(licinfo)
```

For the scripts obfuscated by super mode, there is no package *pytransform*, but an extension *pytransform*. It's similar and more simple

```
from pytransform import get_license_info
licinfo = get_license_info()
print('This obfuscated package is issued by %s' % licinfo['ISSUER'])
print('License information:')
print(licinfo)
```

CHAPTER 4

Examples

Here are some examples.

4.1 Obfuscating and Packing PyQt Application

There is a tool easy-han based on PyQt. Here list the main files:

```
config.json

main.py
ui_main.py
readers/
   __init__.py
   msexcel.py

tests/
vnev/py36
```

Here the shell script used to pack this tool by PyArmor:

By option –e passing extra options to run PyInstaller, to be sure these options work with PyInstaller:

```
cd /path/to/src
pyinstaller --name easy-han --hidden-import comtypes --add-data 'config.json;.' main.

→py
```

(continues on next page)

(continued from previous page)

```
cd dist/easy-han ./easy-han
```

By option -x passing extra options to obfuscate the scripts, there are many .py files in the path tests and vnev, but all of them need not to be obfuscated. By passing option --exclude to exclude them, to be sure these options work with command obfuscate:

```
cd /path/to/src
pyarmor obfuscate -r --exclude vnev --exclude tests main.py
```

Important: The command *pack* will obfuscate the scripts automatically, do not try to pack the obfuscated the scripts.

Note: From PyArmor 5.5.0, it could improve the security by passing the obfuscated option --advanced 1 to enable *Advanced Mode*. For example:

```
pyarmor pack -x " --advanced 1 --exclude tests" foo.py
```

4.2 Running obfuscated Django site with Apache and mod_wsgi

Here is a simple site of Django:

```
/path/to/mysite/
   db.sqlite3
   manage.py
   mysite/
        __init__.py
       settings.py
       urls.py
       wsgi.py
   polls/
        __init__.py
       admin.py
       apps.py
       migrations/
           __init__.py
       models.py
       tests.py
       urls.py
       views.py
```

First obfuscating all the scripts:

```
# Create target path
mkdir -p /var/www/obf_site

# Copy all files to target path, because pyarmor don't deal with any data files
cp -a /path/to/mysite/* /var/www/obf_site/
cd /path/to/mysite
```

(continues on next page)

(continued from previous page)

```
# Obfuscating all the scripts in the current path recursively, specify the entry_
script "wsgi.py"

# The obfuscate scripts will be save to "/var/www/obf_site"

pyarmor obfuscate --src="." -r --output=/var/www/obf_site mysite/wsgi.py
```

Then edit the server configuration file of Apache:

```
WSGIScriptAlias / /var/www/obf_site/mysite/wsgi.py
WSGIPythonHome /path/to/venv

# The runtime files required by pyarmor are generated in this path
WSGIPythonPath /var/www/obf_site

<Directory /var/www/obf_site/mysite>
    <Files wsgi.py>
        Require all granted
    </Files>
</Directory>
```

Finally restart Apache:

apachectl restart

CHAPTER 5

Using Project

Project is a folder include its own configuration file, which used to manage obfuscated scripts.

There are several advantages to manage obfuscated scripts by Project:

- Increment build, only updated scripts are obfuscated since last build
- Filter obfuscated scripts in the project, exclude some scripts
- Obfuscate the scripts with different modes
- More convenient to manage obfuscated scripts

5.1 Managing Obfuscated Scripts With Project

Use command *init* to create a project:

```
cd examples/pybench
pyarmor init --entry=pybench.py
```

It will create project configuration file .pyarmor_config in the current path. Or create project in another path:

```
pyarmor init --src=examples/pybench --entry=pybench.py projects/pybench
```

The project path projects/pybench will be created, and .pyarmor_config will be saved there.

The common usage for project is to do any thing in the project path:

```
cd projects/pybench
```

Show project information:

```
pyarmor info
```

Obfuscate all the scripts in this project by command build:

```
pyarmor build
```

Change the project configuration by command *config*.

For example, exclude the dist, test, the .py files in these folder will not be obfuscated:

```
pyarmor config --manifest "include *.py, prune dist, prune test"
```

By --manifest, the project scripts could be selected exactly, more information refer to the description of the attribute manifest in the section Project Configuration File

Force rebuild:

```
pyarmor build --force
```

Run obfuscated script:

```
cd dist python pybench.py
```

After some scripts changed, just run build again:

```
cd projects/pybench
pyarmor build
```

5.2 Obfuscating Scripts With Different Modes

First configure the different modes, refer to *The Modes of Obfuscated Scripts*:

```
pyarmor config --obf-mod=1 --obf-code=0
```

Then obfuscating scripts in new mode:

```
pyarmor build -B
```

5.3 Obfuscating Some Special Scripts With Child Project

Suppose most of scripts in the project are obfuscated with restrict mode 3, but a few of them need to be obfuscated with restrict mode 2. The child project is right for this case.

1. First create a project in the source path:

```
cd /path/to/src
pyarmor init --entry foo.py
pyarmor config --restrict 3
```

2. Next clone the project configuration file to create a child project named .pyarmor_config-1:

```
cp .pyarmor_config .pyarmor_config-1
```

3. Then config the child project with special scripts, no entry script, and restrict mode 2:

4. Finally build the project and child project:

```
pyarmor build -B
pyarmor build --no-runtime -B .pyarmor_config-1
```

5.4 Project Configuration File

Each project has a configure file. It's a json file named .pyarmor_config stored in the project path.

• name

Project name.

• title

Project title.

• src

Base path to match files by manifest template string.

It could be absolute path, or relative path based on project folder.

· manifest

A string specifies files to be obfuscated, same as MANIFEST.in of Python Distutils, default value is:

```
global-include *.py
```

It means all files anywhere in the src tree matching.

Multi manifest template commands are spearated by comma, for example:

```
global-include *.py, exclude __mainfest__.py, prune test
```

Refer to https://docs.python.org/2/distutils/sourcedist.html#commands

• is_package

Available values: 0, 1, None

When it's set to 1, the basename of *src* will be appended to *output* as the final path to save obfuscated scripts, but runtime files are still in the path *output*

When init a project and no --type specified, it will be set to 1 if there is __init__.py in the path src, otherwise it's None.

· restrict mode

Available values: 0, 1, 2, 3, 4

By default it's set to 1.

Refer to Restrict Mode

entry

A string includes one or many entry scripts.

When build project, insert the following bootstrap code for each entry:

```
from pytransform import pyarmor_runtime
pyarmor_runtime()
```

The entry name is relative to *src*, or filename with absolute path.

Multi entries are separated by comma, for example:

```
main.py, another/main.py, /usr/local/myapp/main.py
```

Note that entry may be NOT obfuscated, if manifest does not specify this entry.

output

A path used to save output of build. It's relative to project path.

· capsule

```
Warning: Removed since v5.9.0
```

Filename of project capsule. It's relative to project path if it's not absolute path.

• obf_code

How to obfuscate byte code of each code object, refer to *Obfuscating Code Mode*:

- 0

No obfuscate

- 1 (Default)

Obfuscate each code object by default algorithm

- 2

Obfuscate each code object by more complex algorithm

• wrap_mode

Available values: 0, 1, None

Whether to wrap code object with try..final block.

The default value is 1, refer to Wrap Mode

• obf_mod

How to obfuscate whole code object of module, refer to *Obfuscating module Mode*:

-0

No obfuscate

- 1 (Default)

Obfuscate byte-code by DES algorithm

· cross_protection

How to proect dynamic library in obfuscated scripts:

- 0

No protection

- 1

Insert proection code with default template, refer to Special Handling of Entry Script

- Filename

Read the template of protection code from this file other than default template.

• runtime_path

None or any path.

When run obfuscated scripts, where to find dynamic library _pytransform. The default value is None, it means it's within the Runtime Package or in the same path of pytransform.py.

It's useful when obfuscated scripts are packed into a zip file, for example, use py2exe to package obfuscated scripts. Set runtime_path to an empty string, and copy *Runtime Files* to same path of zip file, will solve this problem.

• plugins

None or list of string

Extend license type of obfuscated scripts, multi-plugins are supported. For example:

```
plugins: ["check_ntp_time", "show_license_info"]
```

About the usage of plugin, refer to Using Plugin to Extend License Type

• package_runtime

How to save the runtime files:

- 0

Save them in the same path with the obufscated scripts

- 1 (Default)

Save them in the sub-path *pytransform* as a package

· enable_suffix

Note: New in v5.8.7

How to generate runtime package (module) and bootstrap code, it's useful as importing the scripts obfuscated by different developer:

- 0 (Default)

There is no suffix for the name of runtime package (module)

- 1

The name of runtime package (module) has a suffix, for example, pytransform_vax_00001

• platform

Note: New in v5.9.0

A string includes one or many platforms. Multi platforms are separated by comma.

Leave it to None or blank if not cross-platform obfuscating

• license_file

Note: New in v5.9.0

Use this license file other than the default one.

Leave it to None or blank to use the default one.

• bootstrap_code

Note: New in v5.9.0

How to generate *Bootstrap Code* for the obfuscated entry scripts:

- 0

Do not insert bootstrap code into entry script

- 1 (Default)

Insert the bootstrap code into entry script. If the script name is __init__.py, make a relative import with leading dots, otherwise make absolute import.

- 2

The bootstrap code will always be made an absolute import without leading dots in the entry script.

- 3

The bootstrap code will always be made a relative import with leading dots in the entry script.

CHAPTER 6

Man Page

PyArmor is a command line tool used to obfuscate python scripts, bind obfuscated scripts to fixed machine or expire obfuscated scripts.

The syntax of the pyarmor command is:

```
pyarmor <command> [options]
```

The most commonly used pyarmor commands are:

obfuscate	Obfuscate python scripts
licenses	Generate new licenses for obfuscated scripts
pack	Pack obfuscated scripts to one bundle
hdinfo	Show hardware information

The commands for project:

init config build	Create a project to manage obfuscated scripts Update project settings Obfuscate all the scripts in the project
info	Show project information
check	Check consistency of project

The other commands:

benchmark	Run benchmark test in current machine
register	Make registration file work
download	Download platform-dependent dynamic libraries
runtime	Generate runtime package separately

See pyarmor < command > -h for more information on a specific command.

Note: From v5.7.1, the first character is command alias for most usage commands:

```
obfuscate, licenses, pack, init, config, build
```

For example:

```
pyarmor o => pyarmor obfuscate
```

6.1 Common Options

-v, --version Show version information-q, --silent Suppress all normal output

-d, --debug Print exception traceback and debugging message

--home PATH Select home path, generally for multiple registerred pyarmor

These options can be used after *pyarmor*, before sub-command. For example, print debug information to locate the error:

```
pyarmor -d obfuscate foo.py
```

Do not print log in the console:

```
pyarmor --silent obfuscate foo.py
```

Obfuscate scripts with another purchased license:

```
pyarmor --home ~/.pyarmor-2 register pyarmor-keyfile-2.zip
pyarmor --home ~/.pyarmor-2 obfuscate foo.py
```

6.2 obfuscate

Obfuscate python scripts.

SYNOPSIS:

```
pyarmor obfuscate <options> SCRIPT...
```

OPTIONS

-O, --output PATH Output path, default is *dist*

-r, --recursive Search scripts in recursive mode

-s, --src PATH Specify source path if entry script is not in the top most path

--exclude PATH Exclude the path in recusrive mode. Multiple paths are allowed, separated by ",",

or use this option multiple times

--exact Only obfuscate list scripts

--no-bootstrap Do not insert bootstrap code to entry script
 --bootstrap <0,1,2,3> How to insert bootstrap code to entry script

--no-cross-protection Do not insert protection code to entry script

```
--plugin NAME Insert extra code to entry script, it could be used multiple times
```

--platform NAME Distribute obfuscated scripts to other platform

--advanced <0,1,2> Enable advanced mode 1 or super mode 2

--restrict <0,1,2,3,4> Set restrict mode

-n, --no-runtime DO NOT generate runtime files

--package-runtime <0,1> Save the runtime files as package or not

--enable-suffix Generate the runtime package with unique name

--obf-mod <0,1> Disable or enable to obfuscate module

--obf-code <0.1.2> Disable or enable to obfuscate function

--wrap-mode <0,1> Disable or enable wrap mode

--with-license FILENAME Use this licese, special value *outer* means no license

--cross-protection FILENAME Specify customized protection script

DESCRIPTION

PyArmor first checks whether Global Capsule exists in the HOME path. If not, make it.

Then find all the scripts to be obfuscated. There are 3 modes to search the scripts:

- Normal: find all the .py files in the same path of entry script
- Recursive: find all the .py files in the path of entry script recursively
- Exact: only these scripts list in the command line

Note that only the .py files are touched by this command, all the other files aren't copied to output path. If there are many data files in the package, first copy the whole package to the output path, then obfuscate the .py files, thus all the .py files in the output path are overwritten by the obfuscated ones.

If there is an entry script, PyArmor will modify it, insert cross protection code into the entry script. Refer to *Special Handling of Entry Script*

If there is any plugin specified in the command line, PyArmor will scan all the source scripts and inject the plugin code into them before obfuscating. Refer to *How to Deal With Plugins*

Next obfuscate all found scripts, save them in the default output path *dist*.

After that make the *Runtime Package* in the *dist* path.

Finally insert the *Bootstrap Code* into entry script.

If --exact is set, all the scripts in the command line are taken as entry scripts. Otherwise only the first script is entry script.

Option ——src used to specify source path if entry script is not in the top most path. For example:

```
# if no option --src, the "./mysite" is the source path
pyarmor obfuscate --src "." --recursive mysite/wsgi.py
```

Option —plugin is used to extend license type of obfuscated scripts, it will inject the content of plugin script into the obfuscated scripts. The corresponding filename of plugin is *NAME.py*. More information about plugin, refer to *How to Deal With Plugins*, and here is a real example to show usage of plugin *Using Plugin to Extend License Type*

Option —platform is used to specify the target platform of obfuscated scripts if target platform is different from build platform. Use this option multiple times if the obfuscated scripts are being to run many platforms. From v5.7.5, the platform names are standardized, command *download* could list all the available platform names.

6.2. obfuscate 43

Option -- restrict is used to set restrict mode, *Restrict Mode*

Option ——advanced 2 will enable *Super Mode*. In this mode, no runtime files and bootstrap code, only one extension module pytransform is required.

RUNTIME FILES

By default the runtime files will be saved in the separated folder pytransform as package:

```
pytransform/
   __init__.py
   __pytransform.so, or _pytransform.dll in Windows, _pytransform.dylib in MacOS
   pytransform.key
   license.lic
```

But if --package-runtime is θ , they will be saved in the same path with obfuscated scripts as four separated files:

```
pytransform.py
_pytransform.so, or _pytransform.dll in Windows, _pytransform.dylib in MacOS
pytransform.key
license.lic
```

If the option —enable—suffix is set, the runtime package or module name will be pytransform_xxx, here xxx is unique suffix based on the registration code of PyArmor.

BOOTSTRAP CODE

By default, the following *Bootstrap Code* will be inserted into the entry script:

```
from pytransform import pyarmor_runtime
pyarmor_runtime()
```

If the entry script is __init__.py, the *Bootstrap Code* will make a relative import by using leading dots like this:

```
from .pytransform import pyarmor_runtime
pyarmor_runtime()
```

But the option —bootstrap is set to 2, the *Bootstrap Code* always makes absolute import without leading dots. If it is set to 3, the *Bootstrap Code* always makes relative import with leading dots.

If the option --enable-suffix is set, the bootstrap code may like this:

```
from pytransform_vax_000001 import pyarmor_runtime
pyarmor_runtime(suffix='vax_000001')
```

If --no-bootstrap is set, or --bootstrap is 0, then no bootstrap code will be inserted into the entry scripts.

EXAMPLES

• Obfuscate all the .py only in the current path:

```
pyarmor obfuscate foo.py
```

• Obfuscate all the .py in the current path recursively:

```
pyarmor obfuscate --recursive foo.py
```

• Obfuscate all the .py in the current path recursively, but entry script not in top most path:

```
pyarmor obfuscate --src "." --recursive mysite/wsgi.py
```

• Obfuscate a script foo.py only, no runtime files:

```
pyarmor obfuscate --no-runtime --exact foo.py
```

• Obfuscate all the .py in a path recursive, no entry script, no generate runtime package:

```
pyarmor obfuscate --recursive --no-runtime .
pyarmor obfuscate --recursive --no-runtime src/
```

• Obfuscate all the .py in the current path recursively, exclude all the .py in the path build and tests:

```
pyarmor obfuscate --recursive --exclude build,tests foo.py
pyarmor obfuscate --recursive --exclude build --exclude tests foo.py
```

• Obfuscate only two scripts *foo.py*, *moda.py* exactly:

```
pyarmor obfuscate --exact foo.py moda.py
```

• Obfuscate all the .py file in the path mypkg/:

```
pyarmor obfuscate --output dist/mypkg mypkg/__init__.py
```

• Obfuscate all the .py files in the current path, but do not insert cross protection code into obfuscated script dist/foo.py:

```
pyarmor obfuscate --no-cross-protection foo.py
```

• Obfuscate all the .py files in the current path, but do not insert bootstrap code at the beginning of obfuscated script dist/foo.py:

```
pyarmor obfuscate --no-bootstrap foo.py
```

• Insert the content of check_ntp_time.py into foo.py, then obfuscating foo.py:

```
pyarmor obfuscate --plugin check_ntp_time foo.py
```

• Only plugin *assert_armored* is called then inject it into the *foo.py*:

```
pyarmor obfuscate --plugin @assert_armored foo.py
```

• Obfuscate the scripts in Macos and run obfuscated scripts in Ubuntu:

```
pyarmor obfuscate --platform linux.x86_64 foo.py
```

• Obfuscate the scripts in advanced mode:

```
pyarmor obfuscate --advanced 1 foo.py
```

• Obfuscate the scripts with restrict mode 2:

```
pyarmor obfuscate --restrict 2 foo.py
```

• Obfuscate all the .py files in the current path except __init__.py with restrice mode 4:

```
pyarmor obfuscate --restrict 4 --exclude __init__.py --recursive .
```

• Obfuscate a package with unique runtime package name:

6.2. obfuscate 45

```
cd /path/to/mypkg
pyarmor obfuscate -r --enable-suffix --output dist/mypkg __init__.py
```

• Obfuscate scripts by super mode with expired license:

Obfuscate scripts by super mode with customized cross protection scripts, and don't embed license file to extension module, but use outer license.lic:

6.3 licenses

Generate new licenses for obfuscated scripts.

SYNOPSIS:

```
pyarmor licenses <options> CODE
```

OPTIONS

- -O, --output OUTPUT Output path, stdout is supported
- -e, --expired YYYY-MM-DD Expired date for this license
- -d, --bind-disk SN Bind license to serial number of harddisk
- -4, --bind-ipv4 IPV4 Bind license to ipv4 addr
- -m, --bind-mac MACADDR Bind license to mac addr
- -x, --bind-data DATA Pass extra data to license, used to extend license type
- --disable-restrict-mode Disable all the restrict modes
- --enable-period-mode Check license per hour when the obfuscated script is running
- -fixed key,... Bind license to Python interpreter

DESCRIPTION

In order to run obfuscated scripts, it's necessarey to have a *license.lic*. As obfuscating the scripts, there is a default *license.lic* created at the same time. In this license the obfuscated scripts can run on any machine and never expired.

This command is used to generate new licenses for obfuscated scripts. For example:

```
pyarmor licenses --expired 2019-10-10 mycode
```

An expired license will be generated in the default output path plus code name *licenses/mycode*, then overwrite the old one in the same path of obfuscated script:

```
cp licenses/mycode/license.lic dist/pytransform/
```

Another example, bind obfuscated scripts in mac address and expired on 2019-10-10:

```
pyarmor licenses --expired 2019-10-10 --bind-mac 2a:33:50:46:8f tom
cp licenses/tom/license.lic dist/pytransform/
```

Before this, run command *hdinfo* to get hardware information:

```
pyarmor hdinfo
```

By option -x any data could be saved into the license file, it's mainly used to extend license tyoe. For example:

```
pyarmor licenses -x "2019-02-15" tom
```

In the obfuscated scripts, the data passed by -x could be got by this way:

```
from pytransfrom import get_license_info
info = get_license_info()
print(info['DATA'])
```

It also could output the license key in the stdout other than a file:

```
pyarmor --silent licenses --output stdout -x "2019-05-20" reg-0001
```

By option --fixed, the license could be bind to Python interpreter. For example, use special key I to bind the license to current Python interpreter:

```
pyarmor licenses --fixed 1
```

It also could bind the license to many Python interpreters by passing multiple keys separated by comma:

```
pyarmor licenses --fixed 4265050,5386060
```

How to get bind key of Python interpreter, refer to Binding obfuscated scripts to Python interpreter

Do not use this feature in 32-bit Windows, because the bind key is different in different machine, it may be changed even if python is restarted in the same machine.

Note: Here is a real example *Using Plugin to Extend License Type*

6.4 pack

Obfuscate the scripts or project and pack them into one bundle.

SYNOPSIS:

```
pyarmor pack <options> SCRIPT | PROJECT
```

OPTIONS

- **-O, --output PATH** Directory to put final built distributions in.
- **-e, --options OPTIONS** Pass these extra options to *pyinstaller*
- -x, --xoptions OPTIONS Pass these extra options to pyarmor obfuscate
- -s FILE Use external .spec file to pack the scripts
- **--without-license** Do not generate license for obfuscated scripts

6.4. pack 47

--with-license FILE Use this license file other than default one

--clean Remove cached files before packing--debug Do not remove build files after packing

--name Name to assign to the bundled (default: the script's basename)

DESCRIPTION

The command *pack* first calls PyInstaller to generate *.spec* file which name is same as entry script. The options specified by —e will be pass to PyInstaller to generate *.spec* file. It could be any option accepted by PyInstaller except —y, —noconfirm, —n, —name, —distpath, —specpath.

If there is in trouble, make sure the script could be bundled by PyInstaller directly. For example:

```
pyinstaller foo.py
```

So long as PyInstaller could work, just pass those options by -e, the command pack should work either.

Then *pack* will obfuscates all the *.py* files in the same path of entry script recursively. It will call command *obfuscate* with options -r, --output, --package-runtime 0 and the options specified by -x. However if packing a project, *pack* will obfuscate the project by command *build* with option -B, and all the options specified by -x will be ignored. In this case config the project to control how to obfuscate the scripts.

Next pack patches the .spec file so that the original scripts could be replaced with the obfuscated ones.

Finally *pack* call PyInstaller with this pacthed *.spec* file to generate the output bundle with obfuscated scripts. Refer to *How To Pack Obfuscated Scripts*.

If the option ——debug is set, for example:

```
pyarmor pack --debug foo.py
```

The following generated files will be kept, generally all of them are removed after packing end:

```
foo.spec
foo-patched.spec
dist/obf/temp/hook-pytransform.py
dist/obf/*.py # All the obfuscated scripts
```

The patched *foo-patched.spec* could be used by pyinstaller to pack the obfuscated scripts directly, for example:

```
pyinstaller -y --clean foo-patched.spec
```

If some scripts are modified, just obfuscate them again, then run this command to pack them quickly. All the options for command *obfuscate* could be got from the output of command *pack*.

If you'd like to change the final bundle name, specify the option --name directly, do not pass it by the option -e, it need some special handling.

If you have a worked .spec file, just specify it by option -s (in this case the option -e will be ignored), for example:

```
pyarmor pack -s foo.spec foo.py
```

The main script (here it's *foo.py*) must be list in the command line, otherwise *pack* doesn't know where to find the scripts to be obfuscated. More refer to *Bundle obfuscated scripts with customized spec file*

If there are many data files or hidden imports, it's better to write a hook file to find them easily. For example, create a hook file named hook-sys.py:

```
from PyInstaller.utils.hooks import collect_data_files, collect_all
datas, binaries, hiddenimports = collect_all('my_module_name')
datas += collect_data_files('submodule')
hiddenimports += ['_gdbm', 'socket', 'h5py.defs']
datas += [ ('/usr/share/icons/education_*.png', 'icons') ]
```

Then call pack with extra option --additional-hooks-dir . to tell pyinstaller find the hook in the current path:

```
pyarmor pack -e " --additional-hooks-dir ." foo.py
```

More information about pyinstaller hook, refer to https://pyinstaller.readthedocs.io/en/stable/hooks.html# understanding-pyinstaller-hooks

When something is wrong, turn on PyArmor debug flag to print traceback:

```
pyarmor -d pack ...
```

EXAMPLES

• Obfuscate foo.py and pack them into the bundle dist/foo:

```
pyarmor pack foo.py
```

• Remove the build folder, and start a clean pack:

```
pyarmor pack --clean foo.py
```

• Pack the obfuscated scripts by an exists *myfoo.spec*:

```
pyarmor pack -s myfoo.spec foo.py
```

• Pass extra options to run *PyInstaller*:

```
pyarmor pack -e " -w --icon app.ico" foo.py
pyarmor pack -e " --icon images\\app.ico" foo.py
```

• Pass extra options to obfuscate scripts:

```
pyarmor pack -x " --exclude venv --exclude test" foo.py
```

• Pack the obfuscated script to one file and in advanced mode:

```
pyarmor pack -e " --onefile" -x " --advanced 1" foo.py
```

• Pack the obfuscated scripts and expired on 2020-12-25:

```
pyarmor licenses -e 2020-12-25 cy2020
pyarmor pack --with-license licenses/cy2020/license.lic foo.py
```

• Change the final bundle name to my_app other than foo:

```
pyarmor pack --name my_app foo.py
```

• Pack a project with advanced mode:

6.4. pack 49

```
pyarmor init --entry main.py
pyarmor config --advanced 1
pyarmor pack .
```

Note: Since v5.9.0, possible pack one project directly by specify the project path in the command line. For example, create a project in the current path, then pack it:

```
pyarmor init --entry main.py
pyarmor pack .
```

By this way the obfuscated scripts could be fully controlled.

Note: In Windows, use double black splash in extra options. For example:

```
pyarmor pack -e " --icon images\\app.ico" foo.py
```

Important: The command *pack* will obfuscate the scripts automatically, do not try to pack the obfuscated the scripts.

6.5 hdinfo

Show hardware information of this machine, such as serial number of hard disk, mac address of network card etc. The information got here could be as input data to generate license file for obfuscated scripts.

SYNOPSIS:

```
pyarmor hdinfo
```

If pyarmor isn't installed, downlad this tool hdinfo

https://github.com/dashingsoft/pyarmor-core/tree/master/#hdinfo

And run it directly:

```
hdinfo
```

It will print the same hardware information as pyarmor hdinfo

6.6 init

Create a project to manage obfuscated scripts.

SYNOPSIS:

```
pyarmor init <options> PATH
```

OPTIONS

-t, --type <auto,app,pkg> Project type, default value is *auto*

```
-s, --src SRC Base path of python scripts, default is current path
```

-e, --entry ENTRY Entry script of this project

DESCRIPTION

This command will create a project in the specify *PATH*, and a file .*pyarmor_config* will be created at the same time, which is project configuration of JSON format.

If the option --type is set to *auto*, which is the default value, the project type will set to *pkg* if the entry script is $\underline{init}\underline{\ }.py$, otherwise to *app*.

The *init* command will set *is_package* to 1 if the new project is configured as pkg, otherwise it's set to 0.

After project is created, use command *config* to change the project settings.

EXAMPLES

• Create a project in the current path:

```
pyarmor init --entry foo.py
```

• Create a project in the build path *obf*:

```
pyarmor init --entry foo.py obf
```

• Create a project for package:

```
pyarmor init --entry __init__.py
```

• Create a project in the path *obf*, manage the scripts in the path */path/to/src*:

```
pyarmor init --src /path/to/src --entry foo.py obf
```

6.7 config

Update project settings.

--obf-code <0,1,2>

SYNOPSIS:

```
pyarmor config <options> [PATH]
```

OPTIONS

```
--name NAME
                     Project name
                     Project title
--title TITLE
--src SRC
                     Project src, base path for matching scripts
--output PATH
                     Output path for obfuscated scripts
--manifest TEMPLATE Manifest template string
-- entry SCRIPT
                     Entry script of this project
--is-package <0,1>
                     Set project as package or not
--restrict <0,1,2,3,4> Set restrict mode
                     Disable or enable to obfuscate module
--obf-mod <0,1>
```

6.7. config 51

Disable or enable to obfuscate function

- --wrap-mode <0,1> Disable or enable wrap mode
- --advanced <0,1,2> Enable advanced mode 1 or super mode 2
- **--cross-protection <0,1>** Disable or enable to insert cross protection code into entry script, it also could be a filename to specify customized protection script
- --runtime-path RPATH Set the path of runtime files in target machine
- **--plugin NAME** Insert extra code to entry script, it could be used multiple times
- --package-runtime <0,1> Save the runtime files as package or not
- --bootstrap <0,1,2,3> How to insert bootstrap code to entry script
- --enable-suffix <0,1> Generate the runtime package with unique name
- **--with-license FILENAME** Use this license file, special value *outer* means no license

DESCRIPTION

Run this command in project path to change project settings:

```
pyarmor config --option new-value
```

Or specify the project path at the end:

```
pyarmor config --option new-value /path/to/project
```

Option --manifest is comma-separated list of manifest template command, same as MANIFEST.in of Python Distutils.

Option --entry is comma-separated list of entry scripts, relative to src path of project.

If option --plugin is set to empty string, all the plugins will be removed.

For the details of each option, refer to Project Configuration File

EXAMPLES

• Change project name and title:

```
pyarmor config --name "project-1" --title "My PyArmor Project"
```

• Change project entries:

```
pyarmor config --entry foo.py, hello.py
```

• Exclude path *build* and *dist*, do not search .py file from these paths:

```
pyarmor config --manifest "global-include *.py, prune build, prune dist"
```

• Obfuscate script with wrap mode off:

```
pyarmor config --wrap-mode 0
```

• Set plugin for entry script. The content of check_ntp_time.py will be insert into entry script as building project:

```
pyarmor config --plugin check_ntp_time.py
```

• Remove all plugins:

```
pyarmor config --plugin ''
```

6.8 build

Build project, obfuscate all scripts in the project.

SYNOPSIS:

```
pyarmor config <options> [PATH]
```

OPTIONS

-B, --force Force to obfuscate all scripts

-r, --only-runtime Generate extra runtime files only

-n, --no-runtime DO NOT generate runtime files

-O, --output OUTPUT Output path, override project configuration

--platform NAME Distribute obfuscated scripts to other platform

--package-runtime <0,1> Save the runtime files as package or not

DESCRIPTION

Run this command in project path:

```
pyarmor build
```

Or specify the project path at the end:

```
pyarmor build /path/to/project
```

The option ——no-runtime may impact on the *Bootstrap Code*, the bootstrap code will make absolute import without leading dots in entry script.

About option --platform and --package-runtime, refer to command obfuscate

EXAMPLES

• Only obfuscate the scripts which have been changed since last build:

```
pyarmor build
```

• Force build all the scripts:

```
pyarmor build -B
```

• Generate runtime files only, do not try to obfuscate any script:

```
pyarmor build -r
```

• Obfuscate the scripts only, do not generate runtime files:

```
pyarmor build -n
```

• Save the obfuscated scripts to other path, it doesn't change the output path of project settings:

6.8. build 53

pyarmor build -B -O /path/to/other

• Build project in Macos and run obfuscated scripts in Ubuntu:

pyarmor build -B --platform linux.x86_64

6.9 info

Show project information.

SYNOPSIS:

pyarmor info [PATH]

DESCRIPTION

Run this command in project path:

pyarmor info

Or specify the project path at the end:

pyarmor info /path/to/project

6.10 check

Check consistency of project.

SYNOPSIS:

pyarmor check [PATH]

DESCRIPTION

Run this command in project path:

pyarmor check

Or specify the project path at the end:

pyarmor check /path/to/project

6.11 banchmark

Check the performance of obfuscated scripts.

SYNOPSIS:

pyarmor benchmark <options>

OPTIONS:

```
-m, --obf-mode <0,1> Whether to obfuscate the whole module
```

- -c, --obf-code <0,1,2> Whether to obfuscate each function
- -w, --wrap-mode <0,1> Whether to obfuscate each function with wrap mode
- **--debug** Do not remove test path

DESCRIPTION

This command will generate a test script, obfuscate it and run it, then output the elapsed time to initialize, import obfuscated module, run obfuscated functions etc.

EXAMPLES

• Test performance with default mode:

```
pyarmor benchmark
```

• Test performance with no wrap mode:

```
pyarmor benchmark --wrap-mode 0
```

• Check the test scripts which saved in the path .benchtest:

```
pyarmor benchmark --debug
```

6.12 register

Make registration keyfile effect, or show registration information.

SYNOPSIS:

```
pyarmor register [KEYFILE]
```

DESCRIPTION

This command is used to register the purchased keyfile to take it effects:

```
pyarmor register /path/to/pyarmor-regfile-1.zip
```

Show registration information:

```
pyarmor register
```

6.13 download

List and download platform-dependent dynamic libraries.

SYNOPSIS:

```
pyarmor download <options> NAME
```

OPTIONS:

--help-platform Display all available standard platform names

-L, --list FILTER List available dynamic libraries in different platforms

6.12. register 55

-O, --output PATH Save downloaded library to this path

--update Update all the downloaded dynamic libraries

DESCRIPTION

This command mainly used to download available dynamic libraries for cross platform.

List all available standard platform names. For examples:

```
pyarmor download
pyarmor download --help-platform
pyarmor download --help-platform windows
pyarmor download --help-platform linux.x86_64
```

Then download one from the list. For example:

```
pyarmor download linux.armv7
pyarmor download linux.x86_64
```

By default the download file will be saved in the path ~/.pyarmor/platforms with different platform names.

Option --list could filter the platform by name, arch, features, and display the information in details. For examples:

```
pyarmor download --list
pyarmor download --list windows
pyarmor download --list windows.x86_64
pyarmor download --list JIT
pyarmor download --list armv7
```

After *pyarmor* is upgraded, however these downloaded dynamic libraries won't be upgraded. The option —update could be used to update all these downloaded files. For example:

```
pyarmor download --update
```

6.14 runtime

Geneate Runtime Package separately.

SYNOPSIS:

```
pyarmor runtime <options>
```

OPTIONS:

-O, --output PATH Output path, default is dist

-n, --no-package Generate runtime files without package

-i, --inside Generate bootstrap script which is used inside one package

-L, --with-license FILE Replace default license with this file, special value *outer* means no license

--platform NAME Generate runtime package for specified platform
 --enable-suffix Generate the runtime package with unique name
 --super-mode Generate runtime extension module for super mode

DESCRIPTION

This command is used to generate the runtime package separately.

The *Runtime Package* could be shared if the scripts are obufscated by same *Global Capsule*. So generate it once, then need not generate the runtime files when obfuscating the scripts later.

It also generates a bootstrap script pytransform_bootstrap.py in the output path. This script is obfuscated from an empty script, and there is *Bootstrap Code* in it. It's mainly used to run *Bootstrap Code* in the plain script. For example, once it's imported, all the other obfuscated modules could be imported in one plain script:

```
import pytransform_bootstrap
import obf_foo
```

If option ——inside is specified, it will generate bootstrap package pytransform_bootstrap other than one single script.

The option --super-mode is used to generate runtime extension module for *Super Mode*, it's totally different from other modes.

About option --platform and --enable-suffix, refer to command obfuscate

EXAMPLES

• Generate *Runtime Package* pytransform in the default path *dist*:

```
pyarmor runtime
```

• Not generate a package, but four separate files *Runtime Files*:

```
pyarmor runtime -n
```

• Generate bootstrap package dist/pytransform_boostrap:

```
pyarmor runtime -i
```

• Generate *Runtime Package* for platform *armv*7 with expired license:

```
pyarmor licenses --expired 2020-01-01 code-001
pyarmor runtime --with-license licenses/code-001/license.lic --platform linux.

→armv7
```

• Generate runtime module for super mode:

```
pyarmor runtime --super-mode
pyarmor runtime --advanced 2
```

• Generate runtime module for super mode but with outer license.lic:

```
pyarmor runtime --super-mode --with-license outer
```

6.14. runtime 57

Understanding Obfuscated Scripts

7.1 Global Capsule

The .pyarmor_capsule.zip in the HOME path called *Global Capsule*. *PyArmor* will read data from *Global Capsule* when obfuscating scripts or generating licenses for obfuscated scripts.

All the trial version of PyArmor shares one same .pyarmor_capsule.zip, which is created implicitly when executing command pyarmor obfuscate. It uses 1024 bits RSA keys, called *public capsule*.

For purchased version, each user will receive one exclusive private capsule, which use 2048 bits RSA key.

The capsule can't help restoring the obfuscated scripts at all. If your *private capsuel* got by someone else, the risk is that he/she may generate new license for your obfuscated scripts.

Generally this capsule is only in the build machine, it's not used by the obfuscated scripts, and should not be distributed to the end users.

7.2 Obfuscated Scripts

After the scripts are obfuscated by PyArmor, in the dist folder you find all the required files to run obfuscated scripts:

```
dist/
   myscript.py
   mymodule.py

pytransform/
   __init__.py
   __pytransform.so, or _pytransform.dll in Windows, _pytransform.dylib in MacOS
   pytransform.key
   license.lic
```

The obfuscated scripts are normal Python scripts. The module *dist/mymodule.py* would be like this:

```
__pyarmor__(__name__, __file__, b'\x06\x0f...', 1)
```

The entry script *dist/myscript.py* would be like this:

```
from pytransform import pyarmor_runtime
pyarmor_runtime()
__pyarmor__(__name__, __file__, b'\x0a\x02...', 1)
```

7.2.1 Super Obfuscated Scripts

If the scripts are obfuscated by *Super Mode*, it's totaly different. There is only one runtime file, that is extension module pytransform. Only these files in the dist:

```
myscript.py
mymodule.py

pytransform.so or pytransform.dll
```

All the obfuscated scripts would be like this:

```
from pytransform import pyarmor
pyarmor(__name__, __file__, b'\x0a\x02...', 1)
```

Or there is a suffix in extension name, for example:

```
from pytransform_vax_000001 import pyarmor
pyarmor(__name__, __file__, b'\x0a\x02...', 1)
```

Note: The *bootstrap code* is gone in the super mode which may make some users confused. And both *runtime package* and *runtime files* now refer to the extension module pytransform.

7.2.2 Entry Script

In PyArmor, entry script is the first obfuscated script to be run or to be imported in a python interpreter process. For example, __init__.py is entry script if only one single python package is obfuscated.

7.3 Bootstrap Code

The first 2 lines in the entry script called *Bootstrap Code*. It's only in the entry script:

```
from pytransform import pyarmor_runtime
pyarmor_runtime()
```

For the obfuscated package which entry script is __init__.py. The bootstrap code may make a relateive import by leading ".":

```
from .pytransform import pyarmor_runtime
pyarmor_runtime()
```

And there is another form if the runtime path is specified as obfuscating scripts:

```
from pytransform import pyarmor_runtime
pyarmor_runtime('/path/to/runtime')
```

Since v5.8.7, the runtime package may has a suffix. For example:

```
from pytransform_vax_000001 import pyarmor_runtime
pyarmor_runtime(suffix='_vax_000001')
```

7.4 Runtime Package

The package *pytransform* which is in the same folder with obfuscated scripts called *Runtime Packge*. It's required to run the obfuscated script, and it's the only dependency of obfuscated scripts.

Generally this package is in the same folder with obfuscated scripts, but it can be moved anywhere. Only this package in any Python Path, the obfuscated scripts can be run as normal scripts. And all the scripts obfuscated by the same *Global Capsule* could share this package.

There are 4 files in this package:

Before v5.7.0, the runtime package has another form Runtime Files

7.4.1 Runtime Files

They're not in one package, but as four separated files:

```
pytransform.py A normal python module
_pytransform.so/.dll/.lib A dynamic library implements core functions
pytransform.key Data file
license.lic The license file for obfuscated scripts
```

Obviously Runtime Package is more clear than Runtime Files.

Since v5.8.7, the runtime package (module) may has a suffix, for example:

```
pytransform_vax_000001/
    __init__.py
    ...

pytransform_vax_000001.py
...
```

7.5 The License File for Obfuscated Script

There is a special runtime file *license.lic*, it's required to run the obfuscated scripts.

When executing pyarmor obfuscate, a default one will be generated, which allows obfuscated scripts run in any machine and never expired.

In order to bind obfuscated scripts to fix machine, or expire the obfuscated scripts, use command pyarmor licenses to generate a new *license.lic* and overwrite the default one.

Note: In PyArmor, there is another *license.lic*, which locates in the source path of PyArmor. It's required to run *pyarmor*, and issued by me, :)

7.6 Key Points to Use Obfuscated Scripts

- The obfuscated scripts are normal python scripts, so they can be seamless to replace original scripts.
- There is only one thing changed, the *bootstrap code* must be executed before running or importing any obfuscated scripts.
- The runtime package must be in any Python Path, so that the bootstrap code can run correctly.
- The *bootstrap code* will load dynamic library _*pytransform.so/.dll/.dylib* by *ctypes*. This file is dependent-platform, all the prebuilt dynamic libraries list here *Support Platfroms*
- By default the *bootstrap code* searchs dynamic library _*pytransform* in the *runtime package*. Check *pytransform*._*load_library* to find the details.
- If the dynamic library _pytransform isn't within the runtime package, change the bootstrap code:

```
from pytransform import pyarmor_runtime
pyarmor_runtime('/path/to/runtime')
```

Both of runtime files *license.lic* and *pytransform.key* should be in this path either.

• When starts a fresh python interpreter process by *multiprocssing.Process*, *os.exec*, *subprocess.Popen* etc., make sure the *bootstrap code* are called in new process before running any obfuscated script.

More information, refer to How to Obfuscate Python Scripts and How to Run Obfuscated Script

7.7 The Differences of Obfuscated Scripts

There are something changed after Python scripts are obfuscated:

- The major/minor version of Python in build machine should be same as in target machine. Because the scripts will be compiled to byte-code before they're obfuscated, so the obfuscated scripts can't be run by all the Python versions as the original scripts could. Especially for Python 3.6, it introduces word size instructions, and it's totally different from Python 3.5 and before. It's recommeded to run the obfuscated scripts with same major and minor version of Python.
- If Python interpreter is compiled with Py_TRACE_REFS or Py_DEBUG, it will crash to run obfuscated scripts.
- The callback function set by sys.settrace, sys.setprofile, threading.settrace and threading.setprofile will be ignored by obfuscated scripts.
- Some function in the module inspect may not work, and any other module or package may not work if it visits the source or byte code of the obfuscated scripts.
- It will crash to visit the attribute co_const of code object directly if the script is obfuscated in advanced mode.
- The attribute ___file__ of code object in the obfuscated scripts will be <frozen name> other than real filename. So in the traceback, the filename is shown as <frozen name>.

Note that __file__ of moudle is still filename. For example, obfuscate the script foo.py and run it:

```
def hello(msg):
    print(msg)

# The output will be 'foo.py'
print(__file__)

# The output will be '<frozen foo>'
print(hello.__file__)
```

7.8 About Third-Party Interpreter

About third-party interperter, for example Jython, and any embedde Python C/C++ code, they should satisfy the following conditions at least to run the obfuscated scripts:

- They must be load offical Python dynamic library, which should be built from the soure https://github.com/python/cpython, and the core source code should not be modified.
- On Linux, RTLD_GLOBAL must be set as loading libpythonXY.so by dlopen, otherwise obfuscated scripts couldn't work.

Note: Boost::python does not load *libpythonXY.so* with *RTLD_GLOBAL* by default, so it will raise error "No PyCode_Type found" as running obfuscated scripts. To solve this problem, try to call the method *sys.setdlopenflags(os.RTLD_GLOBAL)* as initializing.

• The module *ctypes* must be exists and *ctypes.pythonapi._handle* must be set as the real handle of Python dynamic library, PyArmor will query some Python C APIs by this handle.

CHAPTER 8

How PyArmor Does It

Look at what happened after foo.py is obfuscated by PyArmor. Here are the files list in the output path dist:

```
foo.py

pytransform/
   __init__.py
   _pytransform.so, or _pytransform.dll in Windows, _pytransform.dylib in MacOS
   pytransform.key
   license.lic
```

dist/foo.py is obfuscated script, the content is:

```
from pytransform import pyarmor_runtime
pyarmor_runtime()
__pyarmor__(__name__, __file__, b'\x06\x0f...')
```

There is an extra folder *pytransform* called *Runtime Package*, which are the only required to run or import obfuscated scripts. So long as this package is in any Python Path, the obfuscated script *dist/foo.py* can be used as normal Python script. That is to say:

The original python scripts can be replaced with obfuscated scripts seamlessly.

8.1 How to Obfuscate Python Scripts

How to obfuscate python scripts by PyArmor?

First compile python script to code object:

```
char *filename = "foo.py";
char *source = read_file( filename );
PyCodeObject *co = Py_CompileString( source, "<frozen foo>", Py_file_input );
```

Then change code object as the following way

• Wrap byte code co_code within a try...finally block:

```
wrap header:
         LOAD_GLOBALS
                           N (__armor_enter__) N = length of co_consts
         CALL_FUNCTION 0
         POP TOP
         SETUP_FINALLY X (jump to wrap footer) X = size of original byte code
changed original byte code:
         Increase oparg of each absolute jump instruction by the size of wrap.
⊶header
         Obfuscate original byte code
wrap footer:
        LOAD_GLOBALS
                        N + 1 (\underline{\hspace{0.2cm}} armor \underline{\hspace{0.2cm}} exit \underline{\hspace{0.2cm}})
         CALL_FUNCTION 0
        POP_TOP
         END_FINALLY
```

- Append function names __armor_enter, __armor_exit__ to co_consts
- Increase co_stacksize by 2
- Set CO_OBFUSCAED (0x80000000) flag in co_flags
- Change all code objects in the co_consts recursively

Next serializing reformed code object and obfuscate it to protect constants and literal strings:

```
char *string_code = marshal.dumps( co );
char *obfuscated_code = obfuscate_algorithm( string_code );
```

Finally generate obfuscated script:

```
sprintf( buf, "__pyarmor__(__name__, __file__, b'%s')", obfuscated_code );
save_file( "dist/foo.py", buf );
```

The obfuscated script is a normal Python script, it looks like this:

```
__pyarmor__(__name__, __file__, b'\x01\x0a...')
```

8.2 How to Deal With Plugins

In PyArmor, the plugin is used to inject python code into the obfuscted script before the script is obfuscated, thus the plugin code could be executed when the obfuscated script is running. For example, use a plugin to check internet time:

```
pyarmor obfuscate --plugin check_ntp_time foo.py
```

Why not insert the plugin code into the script directly? Because most of them must be called in the obufscated scripts. For example, get the license information of the obfuscated scripts.

Each plugin is a normal Python script, PyArmor searches it by this way:

- If the plugin has absolute path, then find the corresponding .py file exactly.
- If it has relative path, search the .py file in:
 - The current path
 - \$HOME/.pyarmor/plugins
 - {pyarmor_folder}/plugins
- · Raise exception if not found

When there is plugin specified as obfuscating the script, each comment line will be scanned to find any plugin marker. There are 3 types of plugin marker:

- Plugin Definition Marker
- Plugin Inline Marker
- · Plugin Call Marker

The Plugin Definition Marker looks like this:

```
# {PyArmor Plugins}
```

Generally there is only one in a script, all the plugins will be injected here. It must be one leading comment line, no indentation. If there is no plugin definition marker, none of plugins will be injected.

The others are mainly used to call the function defined in the plugin scripts. There are 3 forms, any comment line with this prefix will be as a plugin marker:

```
# PyArmor Plugin:
# pyarmor_
# @pyarmor_
```

They could appear many times, in any indentation, generally should be behind plugin definition marker.

The first form called *Plugin Inline Marker*, PyArmor just removes this pattern and one following whitespace exactly, and leave the rest part as it is. For example, these are inline markers in the script foo.py:

```
# PyArmor Plugin: check_ntp_time()
# PyArmor Plugin: print('This is plugin code')
# PyArmor Plugin: if sys.flags.debug:
# PyArmor Plugin: check_something():
```

In the dist/foo.py, they'll be replaced as:

```
check_ntp_time()
print('This is plugin code')
if sys.flags.debug:
    check_something()
```

So long as there is any plugin specified in the command line, these replacements will be taken place. If there is no external plugin script, use special plugin name on in the command line. For example:

```
pyarmor obfuscate --plugin on foo.py
```

The second form called *Plugin Call Marker*, it's only used to call function deinfed in the plugin script. Besides, if this function name is not specified as plugin name, PyArmor doesn't touch this marker. For example, obufscate the script by this command:

```
pyarmor obfuscate --plugin check_ntp_time foo.py
```

In the foo.py, only the first marker will be handled, the second marker will be kept as it is, because there is no plugin name specified in the command line as the function name check_multi_mac:

```
# pyarmor_check_ntp_time()
# pyarmor_check_multi_mac()

==>
check_ntp_time()
# pyarmor_check_multi_mac()
```

The last form # @pyarmor_ is almost same as the second, but the comment prefix will be replaced with @, it's mainly used to inject a decorator. For example:

```
# @pyarmor_assert_obfuscated(foo.connect)
def login(user, name):
    foo.connect(user, name)
==>
@assert_obfuscated(foo.connect)
def login(user, name):
    foo.connect(user, name)
```

If the plugin name have a leading @, it will be injected into the script only when it's used in the script, otherwise it's ignored. For example:

```
pyarmor obfuscate --plugin @check_ntp_time foo.py
```

The script foo.py must call plugin function check_ntp_time by one of *Plugin Call Marker*. For example:

```
# pyarmor_check_ntp_time()
```

The *Plugin Inline Marker* doesn't work. For example:

```
# PyArmor Plugin: check_ntp_time()
```

Even this marker will be replaced with <code>check_ntp_time()</code>, but the plugin script will not be injected into the obfuscated script. When it runs, it will complain of no function <code>check_ntp_name</code> found.

8.3 Special Handling of Entry Script

There are 2 extra changes for entry script:

- Before obfuscating, insert protection code to entry script.
- After obfuscated, insert bootstrap code to obfuscated script.

Before obfuscating entry scipt, PyArmor will search the content line by line. If there is line like this:

```
# {PyArmor Protection Code}
```

PyArmor will replace this line with protection code.

If there is line like this:

```
# {No PyArmor Protection Code}
```

PyArmor will not patch this script.

If both of lines aren't found, insert protection code before the line:

```
if __name__ == '__main__'
```

Do nothing if no __main__ line found.

Here it's the default template of protection code:

```
def protect_pytransform():
    import pytransform
    def check_obfuscated_script():
        CO_SIZES = 49, 46, 38, 36
        CO_NAMES = set(['pytransform', 'pyarmor_runtime', '__pyarmor__',
                        '__name__', '__file__'])
        co = pytransform.sys._getframe(3).f_code
        if not ((set(co.co_names) <= CO_NAMES)</pre>
                and (len(co.co_code) in CO_SIZES)):
            raise RuntimeError('Unexpected obfuscated script')
    def check_mod_pytransform():
        def _check_co_key(co, v):
            return (len(co.co_names), len(co.co_consts), len(co.co_code)) == v
        for k, (v1, v2, v3) in {keylist}:
            co = getattr(pytransform, k).{code}
            if not _check_co_key(co, v1):
                raise RuntimeError('unexpected pytransform.py')
            if v2:
                if not _check_co_key(co.co_consts[1], v2):
                    raise RuntimeError('unexpected pytransform.py')
            if v3:
                if not _check_co_key(co.{closure}[0].cell_contents.{code}, v3):
                    raise RuntimeError('unexpected pytransform.py')
    def check_lib_pytransform():
        filename = pytransform.os.path.join({rpath}, {filename})
        size = {size}
        n = size >> 2
        with open(filename, 'rb') as f:
           buf = f.read(size)
        fmt = 'I' * n
        checksum = sum(pytransform.struct.unpack(fmt, buf)) & 0xFFFFFFFF
        if not checksum == {checksum}:
            raise RuntimeError("Unexpected %s" % filename)
    try:
        check_obfuscated_script()
        check_mod_pytransform()
        check_lib_pytransform()
    except Exception as e:
        print("Protection Fault: %s" % e)
        pytransform.sys.exit(1)
protect_pytransform()
```

All the string template $\{xxx\}$ will be replaced with real value by PyArmor.

To prevent PyArmor from inserting this protection code, pass --no-cross-protection as obfuscating the scripts:

```
pyarmor obfuscate --no-cross-protection foo.py
```

After the entry script is obfuscated, the *Bootstrap Code* will be inserted at the beginning of the obfuscated script.

8.4 How to Run Obfuscated Script

How to run obfuscated script dist/foo.py by Python Interpreter?

The first 2 lines, which called Bootstrap Code:

```
from pytransform import pyarmor_runtime
pyarmor_runtime()
```

It will fulfil the following tasks

- Load dynamic library _pytransform by ctypes
- Check license.lic is valid or not
- Add 3 cfunctions to module builtins: __pyarmor__, __armor_enter__, __armor_exit__

The next code line in dist/foo.py is:

```
__pyarmor__(__name__, __file__, b'\x01\x0a...')
```

__pyarmor__ is called, it will import original module from obfuscated code:

```
static PyObject *
    __pyarmor__(char *name, char *pathname, unsigned char *obfuscated_code)
{
    char *string_code = restore_obfuscated_code( obfuscated_code );
    PyCodeObject *co = marshal.loads( string_code );
    return PyImport_ExecCodeModuleEx( name, co, pathname );
}
```

After that, in the runtime of this python interpreter

• __armor_enter__ is called as soon as code object is executed, it will restore byte-code of this code object:

```
static PyObject *
   __armor_enter__(PyObject *self, PyObject *args)
{
    // Got code object
    PyFrameObject *frame = PyEval_GetFrame();
    PyCodeObject *f_code = frame->f_code;

    // Increase refcalls of this code object
    // Borrow co_names->ob_refcnt as call counter
    // Generally it will not increased by Python Interpreter
    PyObject *refcalls = f_code->co_names;
    refcalls->ob_refcnt ++;

    // Restore byte code if it's obfuscated
```

(continues on next page)

(continued from previous page)

```
if (IS_OBFUSCATED(f_code->co_flags)) {
    restore_byte_code(f_code->co_code);
    clear_obfuscated_flag(f_code);
}

Py_RETURN_NONE;
}
```

• __armor_exit__ is called so long as code object completed execution, it will obfuscate byte-code again:

```
static PyObject *
__armor_exit__(PyObject *self, PyObject *args)
   // Got code object
   PyFrameObject *frame = PyEval_GetFrame();
   PyCodeObject *f_code = frame->f_code;
    // Decrease refcalls of this code object
   PyObject *refcalls = f_code->co_names;
   refcalls->ob_refcnt --;
   // Obfuscate byte code only if this code object isn't used by any function
   // In multi-threads or recursive call, one code object may be referenced
   // by many functions at the same time
   if (refcalls->ob_refcnt == 1) {
       obfuscate_byte_code(f_code->co_code);
       set_obfuscated_flag(f_code);
    // Clear f_locals in this frame
   clear_frame_locals(frame);
    Pv RETURN NONE;
```

8.5 How To Pack Obfuscated Scripts

The obfuscated scripts generated by PyArmor can replace Python scripts seamlessly, but there is an issue when packing them into one bundle by PyInstaller:

All the dependencies of obfuscated scripts CAN NOT be found at all

To solve this problem, the common solution is

- 1. Find all the dependencies by original scripts.
- 2. Add runtimes files required by obfuscated scripts to the bundle
- 3. Replace original scripts with obfuscated in the bundle
- 4. Replace entry script with obfuscated one

PyArmor provides command *pack* to achieve this. But in some cases maybe it doesn't work. This document describes what the command *pack* does, and also could be as a guide to bundle the obfuscated scripts by yourself.

First install pyinstaller:

```
pip install pyinstaller
```

Then obfuscate scripts to dist/obf:

```
pyarmor obfuscate --output dist/obf --package-runtime 0 hello.py
```

Next generate specfile, add runtime files required by obfuscated scripts:

If the scripts are obfuscated by super mode, generate specfile by this command:

```
pyi-makespec -p dist/obf --hidden-import pytransform hello.py
```

In windows, the: should be replace with; in the command line.

And patch specfile hello.spec, insert the following lines after the Analysis object. The purpose is to replace all the original scripts with obfuscated ones:

```
src = os.path.abspath('.')
obf_src = os.path.abspath('dist/obf')
for i in range(len(a.scripts)):
   if a.scripts[i][1].startswith(src):
       x = a.scripts[i][1].replace(src, obf_src)
        if os.path.exists(x):
           a.scripts[i] = a.scripts[i][0], x, a.scripts[i][2]
for i in range(len(a.pure)):
    if a.pure[i][1].startswith(src):
        x = a.pure[i][1].replace(src, obf_src)
        if os.path.exists(x):
            if hasattr(a.pure, '_code_cache'):
                with open(x) as f:
                    a.pure._code_cache[a.pure[i][0]] = compile(f.read(), a.pure[i][1],
→ 'exec')
            a.pure[i] = a.pure[i][0], x, a.pure[i][2]
```

Run patched specfile to build final distribution:

```
pyinstaller --clean -y hello.spec
```

Note: Option --clean is required, otherwise the obfuscated scripts will not be replaced because the cached .pyz will be used.

Check obfuscated scripts work:

```
# It works
dist/hello/hello.exe
rm dist/hello/license.lic
```

(continues on next page)

(continued from previous page)

It should not work
dist/hello/hello.exe

CHAPTER 9

Runtime Module pytransform

If you have realized that the obfuscated scripts are black box for end users, you can do more in your own Python scripts. In these cases, pytransform would be useful.

The pytransform module is distributed with obfuscated scripts, and must be imported before running any obfuscated scripts. It also can be used in your python scripts.

9.1 Contents

exception PytransformError

It's DEPRECATED.

This is raised when any pytransform api failed. The argument to the exception is a string indicating the cause of the error.

It's not available in super mode.

get_expired_days()

Return how many days left for time limitation license.

>0: valid in these days

-1: never expired

Note: If the obfuscated script has been expired, it will raise exception and quit directly. All the code in the obfuscated script will not run, so this function will never return 0.

get_license_info()

Get license information of obfuscated scripts.

It returns a dict with keys:

ISSUER: The issuer id EXPIRED: Expired date

- IFMAC: mac address bind to this license
- HARDDISK: serial number of harddisk bind to this license
- IPV4: ipv4 address bind to this license
- DATA: extra data stored in this licese, used by extending license type
- CODE: registration code of this license

The value *None* means no this key in the license.

The key *ISSUER* is introduced from v6.2.5. It will be *trial* if the *license.lic* is generated by trial pyarmor. For purchased pyarmor, it will be the purchased key like *pyarmor-vax-NNNNN*. Note that if the *license.lic* is generated by pyarmor before v6.0.1, it will be None.

Raise Exception if license is invalid, for example, it has been expired.

get_license_code()

Return a string, which is last argument as generating the licenses for obfucated scripts.

Raise Exception if license is invalid.

get_user_data()

Return a string, which is specified by -x as generating the licenses for obfucated scripts.

Return None if no specify -x.

Raise Exception if license is invalid.

get_hd_info(hdtype, size=256)

Get hardware information by hdtype, hdtype could one of

HT_HARDDISK return the serial number of first harddisk

HT_IFMAC return mac address of first network card

HT_IPV4 return ipv4 address of first network card

HT_DOMAIN return domain name of target machine

Raise Exception if something is wrong.

HT_HARDDISK, HT_IFMAC, HT_IPV4, HT_DOMAIN

Constant for *hdtype* when calling get_hd_info()

```
assert_armored(*args)
```

A decorator function used to check each function list in the args is obfuscated.

Raise Exception if any function is not obfuscated.

9.2 Examples

Copy those example code to any script, for example foo.py, obfuscate it, then run the obfuscated script.

Show left days of license

```
from pytransform import get_license_info, get_expired_days
try:
    code = get_license_info()['CODE']
    left_days = get_expired_days()
    if left_days == -1:
        print('This license for %s is never expired' % code)
```

(continues on next page)

(continued from previous page)

```
else:
    print('This license for %s will be expired in %d days' % (code, left_days))
except Exception as e:
    print(e)
```

More usage refer to *Using Plugin to Extend License Type*

Note: Though *pytransform.py* is not obfuscated when running the obfuscated script, it's also protected by *PyArmor*. If it's changed, the obfuscated script will raise protection exception.

Refer to Special Handling of Entry Script

9.2. Examples 77

78

CHAPTER 10

Support Platfroms

The core of PyArmor is written by C, the prebuilt dynamic libraries include the common platforms and some embeded platforms.

Some of them are distributed with PyArmor source package, in these platforms, *pyarmor* could run without downloading anything. Refer to *Prebuilt Libraries Distributed with PyArmor*.

For the other platforms, *pyarmor* first searches path ~/.pyarmor/platforms/SYSTEM/ARCH, SYSTEM.ARCH is one of *Standard Platform Names*. If there is none, PyArmor will download it from remote server automatically. Refer to *The Others Prebuilt Libraries For PyArmor*.

Since v6.2.0, *Super Mode* is introduced, it uses the extension module pytransform directly. All the prebuilt extension files list in the table *The Prebuilt Extensions For Super Mode*

For all the latest platforms, refer to pyarmor-core/platforms/index.json

There may be serveral dynamic libraries with different features in each platform. The platform name with feature number suffix combines an unique name.

Each feature has its own bit

- 1: Anti-Debug
- 2: JIT
- 4: ADV, advanced mode
- 8: SUPER, super mode

For example, windows $.x86_64.7$ means anti-debug(1), JIT(2) and advanced mode(4) supported, windows $.x86_64.0$ means no any feature, so highest speed.

Note that zero feature dynamic library isn't compatible with any featured library. For security reason, the zero feature library uses different alogrithm to obfuscate the scripts. So the platform windows.x86_64.7 can not share the same obfuscated scripts with platform linux.armv7.0.

In some platforms, pyarmor doesn't know it but there is available dynamic library in the table *The Others Prebuilt Libraries For PyArmor*. Just download it and save it in the path ~/.pyarmor/platforms/SYSTEM/ARCH, this command pyarmor -d download will also display this path at the beginning. It's appreicated to send this platform information to jondy.zhao@gmail.com so that it could be recognized by *pyarmor* automatically.

This script will display the required information by *pyarmor*:

```
from platform import *
print('system name: %s' % system())
print('machine: %s' % machine())
print('processor: %s' % processor())
print('aliased terse platform: %s' % platform(aliased=1, terse=1))

if system().lower().startswith('linux'):
    print('libc: %s' % libc_ver())
    print('distribution: %s' % linux_distribution())
```

Contact jondy.zhao@gmail.com if you'd like to run PyArmor in other platform.

10.1 Standard Platform Names

These names are used in the command obfuscate, build, runtime, download to specify platform.

CHAPTER 11

The Modes of Obfuscated Scripts

PyArmor could obfuscate the scripts in many modes in order to balance the security and performance. In most of cases, the default mode works fine. But if the performace is to be bottle-block or in some special cases, maybe you need understand what the differents of these modes and obfuscate the scripts in different mode so that they could work as desired.

11.1 Super Mode

This feature **Super Mode** is introduced from PyArmor 6.2.0. In this mode the structure of PyCode_Type is changed, and byte code or word code is mapped, it's the highest security level in PyArmor. There is only one runtime file required, that is extension pytransform, and the form of obfuscated scripts is unique, no so called *Bootstrap Code* which may make some users confused. All the obfuscated scripts would be like this:

```
from pytransform import pyarmor
pyarmor(__name__, __file__, b'\x0a\x02...', 1)
```

It's recommended to enable this mode in suitable cases. Now only the latest Python versions are supported:

- Python 2.7
- Python 3.7
- Python 3.8

It may support Python 3.5, 3.6 later, but Python 3.0~3.4 is out of plan.

In order to enable it, set option -- advanced 2 to obfuscate:

```
pyarmor obfuscate --advanced 2 foo.py
```

More usage refer to *Using Super Mode*

11.2 Advanced Mode

This feature **Advanced Mode** is introduced from PyArmor 5.5.0. In this mode the structure of PyCode_Type is changed a little to improve the security. And a hook also is injected into Python interpreter so that the modified code objects could run normally. Besides if some core Python C APIs are changed unexpectedly, the obfuscated scripts in advanced mode won't work. Because this feature is highly depended on the machine instruction set, it's only available for x86/x64 arch now. And pyarmor maybe makes mistake if Python interpreter is compiled by old gcc or some other *C* compiles. It's welcome to report the issue if Python interpreter doesn't work in advanced mode.

Take this into account, the advanced mode is disabled by default. In order to enable it, pass option --advanced to command *obfuscate*:

```
pyarmor obfuscate --advanced 1 foo.py
```

Upgrade Notes:

Before upgrading, please estimate Python interpreter in product environments to be sure it works in advanced mode. Here is the guide

https://github.com/dashingsoft/pyarmor-core/tree/v5.3.0/tests/advanced_mode/README.md

It is recommended to upgrade in the next minor version.

Note: In trial version the module could not be obfuscated by advanced mdoe if there are more than about 30 functions in this module, (It still could be obfuscated by non-advanced mode).

11.3 Obfuscating Code Mode

In a python module file, generally there are many functions, each function has its code object.

```
• obf\_code == 0
```

The code object of each function will keep it as it is.

```
• obf code == 1 (Default)
```

In this case, the code object of each function will be obfuscated in different ways depending on wrap mode.

```
• obf_code == 2
```

Almost same as obf_mode 1, but obfuscating bytecode by more complex algorithm, and so slower than the former.

11.4 Wrap Mode

• wrap_mode == 0

When wrap mode is off, the code object of each function will be obfuscated as this form:

(continues on next page)

(continued from previous page)

```
n LOAD_GLOBAL ? (__armor__)
n+3 CALL_FUNCTION 0
n+6 POP_TOP
n+7 JUMP_ABSOLUTE 0
```

When this code object is called first time

- 1. First op is JUMP_ABSOLUTE, it will jump to offset n
- 2. At offset n, the instruction is to call PyCFunction <u>_armor_</u>. This function will restore those obfuscated bytecode between offset 3 and n, and move the original bytecode at offset 0
- 3. After function call, the last instruction is to jump to offset 0. The really bytecode now is executed.

After the first call, this function is same as the original one.

• wrap_mode == 1 (Default)

When wrap mode is on, the code object of each function will be wrapped with try...finally block:

```
LOAD_GLOBALS N (__armor_enter__) N = length of co_consts

CALL_FUNCTION 0

POP_TOP

SETUP_FINALLY X (jump to wrap footer) X = size of original byte code

Here it's obfuscated bytecode of original function

LOAD_GLOBALS N + 1 (__armor_exit__)

CALL_FUNCTION 0

POP_TOP

END_FINALLY
```

When this code object is called each time

- 1. __armor_enter__ will restore the obfuscated bytecode
- 2. Execute the real function code
- 3. In the final block, __armor_exit__ will obfuscate bytecode again.

11.5 Obfuscating module Mode

• obf_mod == 1 (Default)

The final obfuscated scripts would like this:

```
__pyarmor__(__name__, __file__, b'\x02\x0a...', 1)
```

The third parameter is serialized code object of the Python script. It's generated by this way:

```
PyObject *co = Py_CompileString( source, filename, Py_file_input );
obfuscate_each_function_in_module( co, obf_mode );
char *original_code = marshal.dumps( co );
char *obfuscated_code = obfuscate_whole_module( original_code );
sprintf( buffer, "__pyarmor__(__name__, __file__, b'*s', 1)", obfuscated_code );
```

• $obf_mod == 0$

In this mode, the last statement would be like this to keep the serialized module as it is:

```
sprintf( buffer, "__pyarmor__(__name__, __file__, b'%s', 0)", original_code );
```

And the final obfuscated scripts would be:

```
__pyarmor__(__name__, __file__, b'\x02\x0a...', 0)
```

All of these modes only could be changed in the project for now, refer to Obfuscating Scripts With Different Modes

11.6 Restrict Mode

From PyArmor 5.7.0, the *Bootstrap Code* must be in the obfuscated scripts and must be specified as entry script. For example, there are 2 scripts *foo.py* and *test.py* in the same folder, obfuscated by this command:

```
pyarmor obfuscate foo.py
```

Inserting the *bootstrap code* into obfuscated script *dist/test.py* by manual doesn't work, because it's not specified as entry script. It must be run this command to insert the *Bootstrap Code*:

```
pyarmor obfuscate --no-runtime --exact test.py
```

If you need insert the *Bootstrap Code* into plain script, first obfuscate an empty script like this:

```
echo "" > pytransform_bootstrap.py
pyarmor obfuscate --no-runtime --exact pytransform_bootstrap.py
```

Then import pytransform_bootstrap in the plain script.

From PyArmor 5.5.6, there are 4 restrice modes:

• Mode 1

In this mode, obfuscated scripts must be one of the following formats:

```
__pyarmor__(__name__, __file__, b'...')

Or

from pytransform import pyarmor_runtime

pyarmor_runtime()
    __pyarmor__(__name__, __file__, b'...')

Or

from pytransform import pyarmor_runtime

pyarmor_runtime('...')
    __pyarmor__(__name__, __file__, b'...')
```

No any other statement can be inserted into obfuscated scripts.

For examples, the obfuscate scirpt b.py doesn't work, because there is an extra line "print":

```
$ cat b.py
from pytransform import pyarmor_runtime
pyarmor_runtime()
    __pyarmor__(__name__, __file__, b'...')
print(__name__)
```

(continues on next page)

(continued from previous page)

```
$ python b.py
```

• Mode 2

In this mode, except that the obfuscated scripts can't be changed, there are 2 restricts:

- · The entry script must be obfuscated
- The obfuscated scripts could not be imported out of the obfuscated script

For example, this command will raise error if the *foo.py* is obfuscated by restrict mode 2:

```
$ python -c'import foo'
```

• Mode 3

In this mode, there is another restrict base on Mode 2:

- All the functions in the obfuscated script cound not be called out of the obfuscated scripts.
- Mode 4

It's similar with Mode 3, but there is a exception:

• The entry script could be plain script

It's mainly used for obfuscating Python package. The <u>__init__.py</u> is obfuscated by restrict mode 1, all the other scripts are obfuscated by restrict mode 4.

For example, it's the content of *mypkg/__init__.py*

```
# mypkg/
# __init__.py is obfuscated by restrict mode 1
# foo.py is obfuscated by restrict mode 4

# The "foo.hello" could not be called by plain script directly
from .foo import hello

# The "open_hello" could be called by plain scirpt
def open_hello(msg):
    print('This is public hello: %s' % msg)

# The "proxy_hello" could be called by plain scirpt
def proxy_hello(msg):
    print('This is proxy hello: %s' % msg)

# The "foo.hello" could be called by obfuscated "__init__.py"
hello(msg)
```

Note: Mode 2 and 3 could not be used to obfuscate the Python package, because it will be imported from other plain scripts.

Note: Restrict mode is applied to one single script, different scripts could be obfuscated by different restrict mode.

From PyArmor 5.2, Restrict Mode 1 is default.

Obfuscating the scripts by other restrict mode:

11.6. Restrict Mode 87

```
pyarmor obfuscate --restrict=2 foo.py
pyarmor obfuscate --restrict=4 foo.py

# For project
pyarmor config --restrict=2
pyarmor build -B
```

All the above restricts could be disabled by this way if required:

```
pyarmor obfuscate --restrict=0 foo.py

# For project
pyarmor config --restrict=0
pyarmor build -B
```

For more examples, refer to Improving The Security By Restrict Mode

CHAPTER 12

The Performance of Obfuscated Scripts

Run command banchmark to check the performance of obfuscated scripts:

```
pyarmor benchmark
```

Here it's sample output:

```
INFO
        Start benchmark test ...
INFO
        Obfuscate module mode: 1
      Obfuscate code mode: 1
INFO
      Obfuscate wrap mode: 1
INFO
       Benchmark bootstrap ...
INFO
INFO
        Benchmark bootstrap OK.
        Run benchmark test ...
Test script: bfoo.py
Obfuscated script: obfoo.py
load_pytransform: 28.429590911694085 ms
init_pytransform: 10.701080723946758 ms
verify_license: 0.515428636879825 ms
total_extra_init_time: 40.34842417122847 ms
import_no_obfuscated_module: 9.601499631936461 ms
import_obfuscated_module: 6.858413569322354 ms
re_import_no_obfuscated_module: 0.007263492985840059 ms
re_import_obfuscated_module: 0.0058666674116400475 ms
run_empty_no_obfuscated_code_object: 0.015085716201360122 ms
run_empty_obfuscated_code_object: 0.0058666674116400475 ms
run_one_thousand_no_obfuscated_bytecode: 0.003911111607760032 ms
run_one_thousand_obfuscated_bytecode: 0.005307937181960043 ms
```

(continues on next page)

(continued from previous page)

The total extra init time is about 40ms. It includes the time of loading dynamic library, initialzing it and verifing license.

Note that the time of importing obfuscated module is less than of importing no obfuscated module, because the obfuscated scripts has been compiled as byte-code, the original scripts need extra time to compile.

List all available options:

```
pyarmor benchmark -h
```

Specify other options to check the performance in different mode. For example:

```
pyarmor benchmark --wrap-mode 0
```

Look at the scripts used to run benchmark test:

```
pyarmor benchmark --debug
```

All the used files are saved in the folder .benchtest

The Security of PyArmor

PyArmor will obfuscate python module in two levels. First obfucate each function in module, then obfuscate the whole module file. For example, there is a file *foo.py*:

```
def hello():
    print('Hello world!')

def sum(a, b):
    return a + b

if __name == '__main__':
    hello()
    print('1 + 1 = %d' % sum(1, 1))
```

PyArmor first obfuscates the function *hello* and *sum*, then obfuscates the whole moudle *foo*. In the runtime, only current called function is restored and it will be obfuscated as soon as code object completed execution. So even trace code in any c debugger, only a piece of code object could be got one time.

13.1 Cross Protection for _pytransform

The core functions of *PyArmor* are written by c in the dynamic library _*pytransform*. _*pytransform* protects itself by JIT technical, and the obfuscated scripts is protected by _*pytransform*. On the other hand, the dynamic library _*pytransform* is checked in the obfuscated script to be sure it's not changed. This is called Cross Protection.

The dynamic library _pytransform.so uses JIT technical to achieve two tasks:

- Keep the des key used to encrypt python scripts from tracing by any c debugger
- The code segment can't be changed any more. For example, change instruction JZ to JNZ, so that _pytrans-form.so can execute even if checking license failed

How JIT works?

First PyArmor defines an instruction set based on GNU lightning.

Then write some core functions by this instruction set in c file, maybe like this:

```
t_instruction protect_set_key_iv = {
   // function 1
    0x80001,
    0x50020,
    // function 2
    0x80001,
    0xA0F80,
t_instruction protect_decrypt_buffer = {
    // function 1
    0x80021,
    0x52029,
    . . .
    // function 2
    0x80001,
    0xC0901,
}
```

Build _pytransform.so, calculate the codesum of code segment of _pytransform.so

Replace the related instructions with real codesum got before, and obfuscate all the instructions except "function 1" in c file. The updated file maybe likes this:

```
t_instruction protect_set_key_iv = {
   // plain function 1
   0x80001,
   0x50020,
   // obfuscated function 2
   0xXXXXX,
   0xXXXXX,
t_instruction protect_decrypt_buffer = {
   // plain function 1
   0x80021,
   0x52029,
    . . .
   // obfuscated function 2
   0xXXXXX,
    0xXXXXX,
}
```

Finally build _pytransform.so with this changed c file.

When running obfuscated script, _pytransform.so loaded. Once a proected function is called, it will

1. Generate code from function 1

2. Run function 1:

- · check codesum of code segment, if not expected, quit
- check tickcount, if too long, quit
- check there is any debugger, if found, quit
- clear hardware breakpoints if possible
- restore next function function 2
- 3. Generate code from function 2
- 4. Run function 2, do same thing as function 1

After repeat some times, the real code is called. All of that is to be sure there is no breakpoint in protection code.

In order to protect _pytransform in Python script, some extra code will be inserted into the entry script, refer to Special Handling of Entry Script

CHAPTER 14

When Things Go Wrong

When there is in trouble, try to solve it by these ways.

As running pyarmor:

- Check the console output, is there any wrong path, or any odd information
- Run *pyarmor* with debug option –d to get more information. For example:

```
pyarmor -d obfuscate --recurisve foo.py
```

• Set Python debug flag to get more information. For example:

```
PYTHONDEBUG=y pyarmor obfuscate --recurisve foo.py

# In Windows
set PYTHONDEBUG=y
pyarmor obfuscate --recurisve foo.py
```

As running the obfuscated scripts:

• Turn on Python debug option by -d to print more information. For example:

```
python -d obf_foo.py
```

After python debug option is on, there will be a log file *pytransform.log* generated in the current path, which includes more debug information.

14.1 Segment fault

In the following cases, obfuscated scripts will crash

- · Running obfuscated script by the debug version Python
- Obfuscating scripts by Python 2.6 but running the obfuscated scripts by Python 2.7

After PyArmor 5.5.0, some machines may be crashed because of advanced mode. A quick workaround is to disable advanced mode by editing the file pytransform.py which locates in the installed path of pyarmor, in the function <code>_load_library</code>, uncomment about line 202. The final code looks like this:

```
# Disable advanced mode if required
m.set_option(5, c_char_p(1))
```

14.2 Bootstrap Problem

14.2.1 Could not find _pytransform

Generally, the dynamic library *_pytransform* is in the *Runtime Package*, before v5.7.0, it's in the same path of obfuscated scripts. It may be:

- pytransform.so in Linux
- _pytransform.dll in Windows
- _pytransform.dylib in MacOS

First check whether the file exists. If it exists:

• Check the permissions of dynamic library

If there is no execute permissions in Windows, it will complain: [Error 5] Access is denied

• Check whether *ctypes* could load *_pytransform*:

```
from pytransform import _load_library
m = _load_library(path='/path/to/dist')
```

• Try to set the runtime path in the *Bootstrap Code* of entry script:

```
from pytransform import pyarmor_runtime
pyarmor_runtime('/path/to/dist')
```

Still doesn't work, report an issue

14.2.2 ERROR: Unsupport platform linux.xxx

In some machines *pyarmor* could not recognize the platform and raise error. If there is available dynamic library in the table *Table-2*. *The Others Prebuilt Libraries For PyArmor*. Just download it and save it in the path ~/. pyarmor/platforms/SYSTEM/ARCH, this command pyarmor -d download will also display this path at the beginning.

If there is no any available one, contact jondy.zhao@gmail.com if you'd like to run pyarmor in this platform.

14.2.3 /lib64/libc.so.6: version 'GLIBC 2.14' not found

In some machines there is no GLIBC_2.14, it will raise this exception.

One solution is patching _pytransform.so by the following way.

First check version information:

```
readelf -V /path/to/_pytransform.so
...

Version needs section '.gnu.version_r' contains 2 entries:
Addr: 0x00000000000056e8 Offset: 0x0056e8 Link: 4 (.dynstr)
000000: Version: 1 File: libdl.so.2 Cnt: 1
0x0010: Name: GLIBC_2.2.5 Flags: none Version: 7
0x0020: Version: 1 File: libc.so.6 Cnt: 6
0x0030: Name: GLIBC_2.7 Flags: none Version: 8
0x0040: Name: GLIBC_2.14 Flags: none Version: 6
0x0050: Name: GLIBC_2.4 Flags: none Version: 5
0x0060: Name: GLIBC_2.3.4 Flags: none Version: 4
0x0070: Name: GLIBC_2.2.5 Flags: none Version: 3
0x0080: Name: GLIBC_2.3 Flags: none Version: 2
```

Then replace the entry of GLIBC_2.14 with GLIBC_2.2.5:

- Copy 4 bytes at 0x56e8+0x10=0x56f8 to 0x56e8+0x40=0x5728
- Copy 4 bytes at 0x56e8+0x18=0x5700 to 0x56e8+0x48=0x5730

Here are sample commands:

```
xxd -s 0x56f8 -1 4 _pytransform.so | sed "s/56f8/5728/" | xxd -r - _pytransform.so xxd -s 0x5700 -1 4 _pytransform.so | sed "s/5700/5730/" | xxd -r - _pytransform.so
```

Note: From v5.7.9, this patch is not required. In cross-platform all you need to do is specify the platform to *centos6.x86_64* to fix this issue. For example:

```
pyarmor obfuscate --platform centos6.x86_64 foo.py
```

14.3 Obfuscating Scripts Problem

14.3.1 Warning: code object xxxx isn't wrapped

It means this function isn't been obfuscated, because it includes some special instructions.

For example, there is 2-bytes instruction *JMP 255*, after the code object is obfuscated, the operand is increased to 267, and the instructions will be changed to:

```
EXTEND 1
JMP 11
```

In this case, it's complex to obfuscate the code object with wrap mode. So the code object is obfuscated with non wrap mode, but all the other code objects still are obfuscated with wrap mode.

In current version add some unused code in this function so that the operand isn't the critical value may avoid this warning.

Note: Before v5.5.0, in this case the code object is left as it is.

14.3.2 Code object could not be obufscated with advanced mode 2

Because this function includes some jump instructions that couldn't be handled. In this case, just refine this function, make sure the first statement will not generate jump instruction. For example, assignment, function call or any simple statement. However, the compound statements, for examples, *try*, *for*, *if*, *with*, *while* etc. will generate the jump instructions. If there is no anyway to refactor the function, insert the following statement at the beginning of this function:

```
[None, None]
```

It will generate some instructions but doesn't change anything.

14.3.3 Error: Try to run unauthorized function

If there is any file *license.lic* or *pytransform.key* in the current path, pyarmor maybe reports this error. One solution is to remove all of that files, the other solution to upgrade PyArmor to v5.4.5 later.

14.3.4 'XXX' codec can't decode byte 0xXX

Add the exact source encode at the begin of the script. For example:

```
# -*- coding: utf-8 -*-
```

Refer to https://docs.python.org/2.7/tutorial/interpreter.html#source-code-encoding

14.3.5 Why plugin doesn't work

If the plugin script doesn't work as expected, first check the plugin script could be injected into the entry script by set Python debug flag:

```
# In linux
export PYTHONDEBUG=y
# In Windows
set PYTHONDEBUG=y

pyarmor obfuscate --exact --plugin check_ntp_time foo.py
```

It will generate patched file foo.py.pyarmor-patched, make sure the content of plugin script has been inserted into the right place, and the verify function will be executed.

14.4 Running Obfuscated Scripts Problem

14.4.1 The *license.lic* generated doesn't work

The key is that the capsule used to obfuscate scripts must be same as the capsule used to generate licenses.

The *Global Capsule* will be changed if the trial license file of *PyArmor* is replaced with normal one, or it's deleted occasionally (which will be generated implicitly as running command *pyarmor obfuscate* next time).

In any cases, generating new license file with the different capsule will not work for the obfuscated scripts before. If the old capsule is gone, one solution is to obfuscate these scripts by the new capsule again.

14.4.2 NameError: name '__pyarmor__' is not defined

No Bootstrap Code are executed before importing obfuscated scripts.

When creating new process by *Popen* or *Process* in mod *subprocess* or *multiprocessing*, to be sure that *Bootstrap Code* will be called before importing any obfuscated code in sub-process. Otherwise it will raise this exception.

14.4.3 Marshal loads failed when running xxx.py

- 1. Check whether the version of Python to run obfuscated scripts is same as the version of Python to obfuscate script
- 2. Run obfuscated script by *python -d* to show more error message.
- 3. Be sure the capsule used to generated the license file is same as the capsule used to obfuscate the scripts. The filename of the capsule will be shown in the console when the command is running.

14.4.4 _pytransform can not be loaded twice

When the function pyarmor_runtime is called twice, it will complaint _pytransform can not be loaded twice

For example, if an obfuscated module includes the following lines:

```
from pytransform import pyarmor_runtime
pyarmor_runtime()
__pyarmor__(....)
```

When importing this module from entry script, it will report this error. The first 2 lines should be in the entry script only, not in the other module.

This limitation is introduced from v5.1, to disable this check, just edit *pytransform.py* and comment these lines in function *pyarmor_runtime*:

```
if _pytransform is not None:
    raise PytransformError('_pytransform can not be loaded twice')
```

Note: This limitation has been removed from v5.3.5.

14.4.5 Check restrict mode failed

Use obfuscated scripts in wrong way, by default all the obfuscated scripts can't be changed any more.

Besides packing the obfuscated scripts will report this error either. Do not pack the obfuscated scripts, but pack the plain scripts directly.

For more information, refer to Restrict Mode

14.4.6 Protection Fault: unexpected xxx

Use obfuscated scripts in wrong way, by default, all the runtime files can't be changed any more. Do not touch the following files

• pytransform.py

_pytransform.so/.dll/.dylib

For more information, refer to Special Handling of Entry Script

14.4.7 Run obfuscated scripts reports: Invalid input packet

If the scripts are obfuscated in different platform, check the notes in Distributing Obfuscated Scripts To Other Platform

Before v5.7.0, check if there is any of *license.lic* or *pytransform.key* in the current path. Make sure they're generated for the obfuscated scripts. If not, rename them or move them to other path.

Because the obfuscated scripts will first search the current path, then search the path of runtime module *pytransform.py* to find the file *license.lic* and *pytransform.key*. If they're not generated for the obfuscated script, this error will be reported.

14.4.8 OpenCV fails because of NEON - NOT AVAILABLE

In some Raspberry Pi platform, run the obfuscated scripts to import OpenCV fails:

One solution is to specify optioin --platform to *linux.armv7.0*:

```
pyarmor obfuscate --platform linux.armv7.0 foo.py
pyarmor build --platform linux.armv7.0
pyarmor runtime --platform linux.armv7.0
```

The other solution is to set environment variable PYARMOR_PLATFORM to linux.armv7.0. For examples:

```
PYARMOR_PLATFORM=linux.armv7.0 pyarmor obfuscate foo.py
PYARMOR_PLATFORM=linux.armv7.0 pyarmor build

Or,

export PYARMOR_PLATFORM=linux.armv7.0
pyarmor obfuscate foo.py
pyarmor build
```

14.5 Packing Obfuscated Scripts Problem

14.5.1 No module name pytransform

If report this error as running command *pyarmor pack*:

- Make sure the script specified in the command line is not obfuscated
- Run pack with extra option --clean to remove cached myscript.spec:

```
pyarmor pack --clean foo.py
```

14.6 PyArmor Registration Problem

14.6.1 Purchased pyarmor is not private

Even obfuscated with purchased version, license from trial version works:

- Make sure command *pyarmor register* shows correct registration information
- Make sure Global Capsule file ~/.pyarmor_capsule.zip is same as the one in the keyfile pyarmor-regfile-1.zip
- Try to reboot system.

14.7 Known Issues

14.7.1 Obfuscate scripts in cross platform

From v5.6.0 to v5.7.0, there is a bug for cross platform. The scripts obfuscated in linux64/windows64/darwin64 don't work after copied to one of this target platform:

```
armv5, android.aarch64, ppc64le, ios.arm64, freebsd, alpine, alpine.arm, poky-i586
```

14.8 Misc. Questions

14.8.1 How easy is to recover obfuscated code

If someone tries to break the obfuscation, he first must be an expert in the field of reverse engineer, and be an expert of Python, who should understand the structure of code object of python, how python interpreter each instruction. If someone of them start to reverse, he/she must step by step thousands of machine instruction, and research the algorithm by machine codes. So it's not an easy thing to reverse pyarmor.

CHAPTER 15

License

The software is distributed as Free To Use But Restricted. Free trial version never expires, the limitations are

- The maximum size of code object is 32756 bytes in trial version
- The scripts obfuscated by trial version are not private. It means anyone could generate the license file which works for these obfuscated scripts.
- In trial version if obfuscating the Python scripts in advanced modes, the limitation is no more than about 32 functions (code objects) in one module.
- Without permission the trial version may not be used for the Python scripts of any commercial product.

About the license file of obfuscated scripts, refer to The License File for Obfuscated Script

A registration code is required to obfuscate big code object or generate private obfuscated scripts.

There are 2 basic types of licenses issued for the software. These are:

• A personal license for home users. The user purchases one license to use the software on his own computer.

Home users may use their personal license to obfuscate all the python scripts which are property of the license owner, to generate private license files for the obfuscated scripts and distribute them and all the required files to any other machine or device.

Home users could NOT obfuscate any python script which is NOT property of the license owner.

• A enterprise license for business users. The user purchases one license to use the software for one product serials of an organization.

One product serials include the current version and any other latter versions of the same product.

Business users may use their enterprise license on all computers and embedded devices to obfuscate all the python scripts of this product serials, to generate private license files for these obfuscated scripts and distribute them and all the required files to any other machine and device.

Without permission of the software owner the license purchased for one product serials should not be used for other product serials. Business users should purchase new license for different product serials.

In any case, the software is only used to obfuscate the Python scripts owned by the authorized person or enterprise. For example, if PyCharm purchases one license, it's no problem to obufscate any Python script of

PyCharm self, but it's not allowed to apply this license to the Python scripts just written in the PyCharm by someone else.

15.1 Purchase

To buy a license, please visit the following url

https://order.shareit.com/cart/add?vendorid=200089125&PRODUCT{[}300871197{]}=1

A registration keyfile generally named "pyarmor-regfile-1.zip" will be sent to your email immediately after payment is completed successfully. There are 3 files in the archive:

- REAME.txt
- license.lic (registration code)
- .pyarmor_capsule.zip (private capsule)

Run the following command to take this keyfile effects:

pyarmor register /path/to/pyarmor-regfile-1.zip

Check the registeration information:

pyarmor register

If the version of PyArmor < 5.6, unzip this registration file, then

- Copy "license.lic" in the archive to the installed path of PyArmor
- Copy ".pyarmor_capsule.zip" in the archive to user HOME path

After the registration keyfile takes effect, you need obfuscate the scripts again.

Important: The registration code is valid forever, it can be used permanently. But it may not work with new versions, although up to now it works with all of versions.

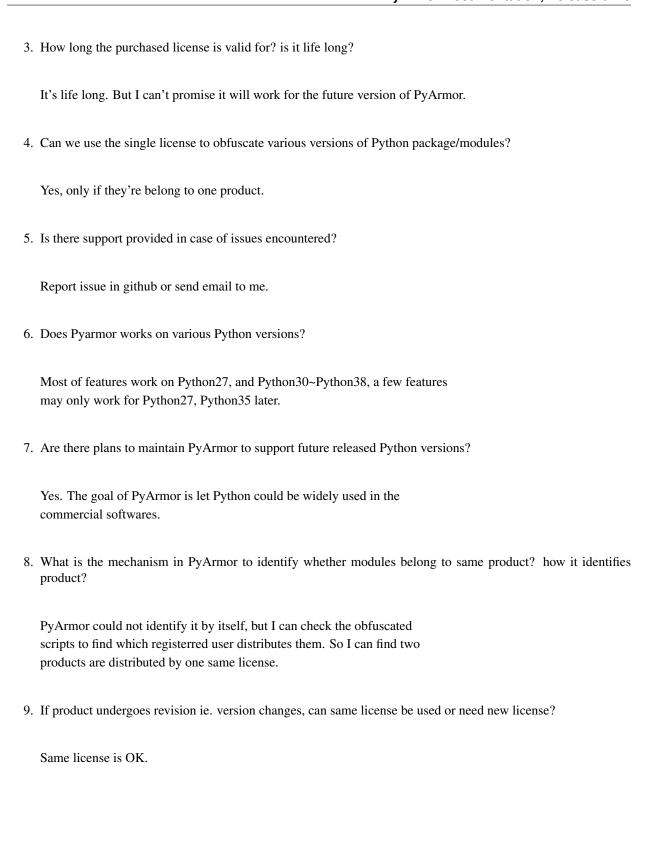

15.2 Q & A

1. Single PyArmor license purchased can be used on various machines for obfuscation? or its valid only on one machine? Do we need to install license on single machine and distribute obfuscate code?

It can be used on various machines, but one license only for one product.

2. Single license can be used to obfuscate Python code that will run various platforms like windows, various Linux flavors?

For all the features of current version, it's yes. But in future versions, I'm not sure one license could be used in all of platforms supported by PyArmor.

15.2. Q & A 105

106 Chapter 15. License

CHAPTER 16

Change Logs

16.1 6.2.6

• Fix get_license_info issue: the value of CODE is blank

16.2 6.2.5

- Add option -with-license in the command build
- Fix pack issue: the option -with-license doesn't work in super mode
- If the code object couldn't be obfuscated in advanced 2 (super mode), fix it automatically by inserting one redundant line [None, None] at the beginning of this code object
- Ignore case when checking mac address if the license is bind to network card
- Add key ISSUER in the return value of get_license_info

16.3 6.2.4

- Fix pack issue for Mac in super mode: RuntimeError: unexpected pytransform.so
- Fix pack issue for windows 32-bit system: the default license doesn't work in other machines, it complains of *License is not for this machine*

16.4 6.2.3

- Add common option --home, so PYARMOR_HOME can be set in the command line
- Fix pack issue: pack command may not work with super mode

16.5 6.2.2

- Fix advanced mode issue: advanced mode 1 doesn't work in pyenv and some platforms
- Fix issue(#244): when obfuscating the scripts for cross platform and only one platform specified, the obfuscated scripts raise unexpected protection error.

16.6 6.2.1

• Fix issue(#244): when specify only one platform the obfuscated scripts raise exception:

```
[Errno 2] No such file or directory: 'xxx/_pytransform.so'
```

Super mode supports windows.x86, linux.x86, linux.aarch64, linux.aarch32, linux.armv7

16.7 6.2.0

In this version, **super mode** is introduced to improve the security. In this mode the structure of PyCode_Type is changed, and byte code or word code is mapped, it's the highest security level in PyArmor. There is only one runtime file required, that is extension module pytransform, and the form of obfuscated scripts is unique, no so called *Bootstrap Code* which may make some users confused. All the obfuscated scripts would be like this

```
from pytransform import pyarmor
pyarmor(__name__, __file__, b'\x0a\x02...', 1)
```

It's recommended to enable this mode in suitable cases. Now only the latest Python versions are supported:

- Python 2.7
- Python 3.7
- Python 3.8

It may support Python 3.5, 3.6 later, but Python 3.0~3.4 is out of plan.

- Add new option -obf-mode, -obf-code, -wrap-mode to command obfuscate
- Add new value 2 for option -advanced to enable super mode, refer to Using Super Mode
- Fix multiprocessing issue: ValueError: __mp_main__. _spec__ is None (#232)
- The command runtime will generate default protection script pytransform_protection.py
- Add new option -cross-protection to command obfuscate to specify customized protection script
- The default cross protection code will not be injected the entry script if *-no-runtime* is specified as obfuscating the scripts. In this case, use option *-cross-protection* to specify one protection script
- Change the default capsule location from ~/.pyarmor_capsule.zip to ~/.pyarmor/.pyarmor_capsule.zip
- Add new functions get_user_data, assert_armored in runtime module pytransform
- Document how to store runtime file license.lic to any location
- Remove the trailing dot from harddisk serial number, it may impact the license verified.

16.8 6.1.0

- Add external plugin script assert_armored.py
- Enhance the command *licenses*:
 - The final argument could be empty, for example, *pyarmor licenses* will generate a default license to *licenses/pyarmor/license.lic*
 - If the output is end with *license.lic*, it will not append any other path, just save it as it is. For example, *pyarmor licenses -O dist/license.lic* will save the final output to *dist/license.lic*
 - Add new option -fixed, and document how to use this option to improve the security
- In command pack, the default license will be generated with -fixed to improve the security

16.9 6.0.2

- Refine the obfuscated code object to improve security
- Refine plugin code to make it clear https://pyarmor.readthedocs.io/en/latest/how-to-do.html# how-to-deal-with-plugins
- Add internal plugin assert_armored and document basic usage https://pyarmor.readthedocs.io/en/latest/advanced.html#checking-imported-function-is-obfuscated

16.10 6.0.1

- Fix restrict mode 3 bug: the obfuscated script crashes or complains of this error: *This function could not be called from the plain script* (#219)
- Fix bug: the obfuscated script raises unknown opcode error when the script is obfuscated by *obf_code=2* if there is recursive function call
- Fix command *init* and *config* bug: the entry script is set to . other than empty when passing --entry=""
- Fix bug: the traceback will print very long line if the obfuscated script raises exception
- Fix bug: in some special cases the obfuscated scripts which are obfuscated with --enable-suffix still conflict with other obfuscated packages
- Refine the error message as violating restrict mode
- The obfuscated script will raise exception *RuntimeError* other than quit directly when something is wrong **Now** it will print a pretty traceback to find where is the problem
- When generating *license.lic* for the obfuscated scripts, the license version information will be embedded into the license file implicitly
- Do not transfer exception type to PytransformError as pyarmor initializes failed

Upgrade notes:

The license file generated by this version doesn't work with the old obfuscated scripts. There are 2 solutions for this case:

- Still generating the license file with old version pyarmor
- · Or obfuscating the scrips again by new version pyarmor

16.8. 6.1.0

16.11 5.9.8

- Fix restrict mode 3 bug: the obfuscated function failed if it's called from generator function even in the obfuscated script.
- In pack command it will try to use the encoding *coding: xxx* in the first comment line of *.spec* file

16.12 5.9.7

- Fix pack issue: it will raise UnicodeDecodeError when the source path includes non-ascii characters(#217)
- Fix obfuscate issue for Python2: it will raise *UnicodeDecodeError* when the source path includes non-ascii characters
- Refine pack command: it will print the output of PyInstaller to the console either

16.13 5.9.6

• Refine pack command. Now it's easy to pack the obfuscated scripts with an exists .spec file, just specify it by -s, refer to https://pyarmor.readthedocs.io/en/latest/advanced.html# bundle-obfuscated-scripts-with-customized-spec-file

16.14 5.9.5

- Change the plugin search policy, do not support enviorment variable *PYARMOR_PLUGIN*, but search folder *plugins* in the pyarmor package path.
- Add a new path *plugins* in the package source, there are several common plugins. So it's easy to check internet time by this way:

```
pyarmor obfuscate --plugin check_ntp_time foo.py
```

Before that both of these lines should be inserted into foo.py:

```
# {PyArmor Plugins}
# PyArmor Plugin: check_ntp_time()
```

- Fix pack bug: pyi-makespec: error: unrecognized arguments: -y if extra options are passed
- Document command pack in details: https://pyarmor.readthedocs.io/en/latest/man.html#pack

16.15 5.9.4

- Fix pack issue: pyi-makespec doesn't work
- Add new platform: uclibc-armv7
- Fix issue: guess encoding failed if there are non-ascii characters in the second line
- · Document how to work with Nuitka, https://pyarmor.readthedocs.io/en/latest/advanced.html#work-with-nuitka

16.16 5.9.3

- Add new option -- enable-period-mode in the command licenses
- When running the obfuscated scripts it will check license periodly (per hour) if the option —enable—period—mode is set in the license file

16.17 5.9.2

- Fix bug: the command pyarmor runtime –platform alpine.x86_64 raises error (#201)
- Fix bug: the platform *linux.armv6* doesn't work in Raspberry PI Zero W, rebuild the dynamic library with -march=armv6 -mfloat-abi=hard -marm

16.18 5.9.1

- Python debugger and profile tool could work with the plain python scripts even if the obfuscated packages are imported. Note that the obfuscated scripts still couldn't be traced.
- Refine pack command, use pyi-makespec to generate .spec file
- Fix advanced mode fails in some linux platforms
- Support platform *linux.armv6*
- Fix python38 issue: in the wrap mode the footer block isn't executed

16.19 5.9.0

pyarmor-webui is published as a separated package, it has been removed from source package of pyarmor. Now it's a full feature webui, and could be installed by *pip install pyarmor-webui*.

- Support environment variable *PYARMOR_HOME* as one extra path to find the *license.lic* of pyarmor. Now the search order is:
 - In the package path of pyarmor
 - \$PYARMOR HOME/.pyarmor/license.lic
 - \$HOME/.pyarmor/license.lic
 - \$USERPROFILE/.pyarmor/license.lic (Only for Windows)
- In command *licenses* if option *output* is set, do not append extra path *licenses* in the final output path
- In command *obfuscate* with option *-exact*, all the scripts list in the command line will be taken as entry script.
- The last argument in command pack could be a project path or .json file
- Add new option -- name in the command pack
- Add new project attribute license_file, bootstrap_code
- Add new option --with-license, --bootstrap in the command config
- Add new option --bootstrap in the command *obfuscate*

16.16. 5.9.3

- The options --package-runtime doesn't support 2 and 3, use --bootstrap=2 or --bootstrap=3 instead
- For command *licenses* the generated license could be printed to stdout by setting the option —output to stdout

16.20 5.8.9

- Fix cross platform issue for vs2015.x86 and vs2015.x86_64
- In command config add option --advanced as alias of --advanced-mode

16.21 5.8.8

• Fix issue: the obfuscated scripts will crash when importing the packages obfuscated with advanced mode by other registered pyarmor

16.22 5.8.7

In this version, the scripts could be obfuscated with option --enable-suffix, then the name of the runtime package and builtin functions will be unique. By this way the scripts obfuscated by different capsule could run in the same Python interpreter.

For example, the bootstrap code may like this with suffix _vax_000001:

```
from pytransform_vax_000001 import pyarmor_runtime
pyarmor_runtime(suffix="_vax_000001")
```

Refer to https://pyarmor.readthedocs.io/en/latest/advanced.html#obfuscating-package-no-conflict-with-others

- Add option --enable-suffix in the commands obfuscate, config and runtime
- Add option —with—license in the command pack
- Fix issue: the executable file made by pack raises protection fault exception on MacOSX

16.23 5.8.6

- Raise exception other than sys.exit(1) when pyarmor_runtime fails
- Refine cross protection code to improve the security
- Fix issue: advanced mode fails in some MacOSX machines with python2.7

16.24 5.8.5

- Add platform data file index.json to source package
- Refine core library for platform MacOSX

16.25 5.8.4

- Fix issue: advanced mode doesn't work in some MacOSX machines.
- Fix issue: can't get the serial number of SSD harddisk in MacOSX platform

16.26 5.8.3

• Fix issue: the _pytransform.dll for windows.x86_64 is not latest

16.27 5.8.2

- Fix issue: the option --exclude in command *obfuscate* could not exclude .py files
- Refine command pack

16.28 5.8.1

- Fix issue: check license failed if there is no environment variable *HOME* in linux platform
- Add new value 3 for option —package—runtime, the bootstrap code will always use relative import with an extra leading dot
- The command runtime also generates bootstrap script pytransform_bootstrap.py
- Add option --inside in command runtime to generate bootstrap package pytransform_bootstrap
- Document how to run unittest of obfuscated scripts, refer to https://pyarmor.readthedocs.io/en/latest/advanced. html#run-unittest-of-obfuscated-scripts

16.29 5.8.0

- Move the license file of pyarmor from the install path of pyarmor package to user home path ~/.pyarmor
- Refine error messages so that the users could solve most of problems by the hints.
- Refine command pack, use hook hook-pytransform.py to add the runtime files.
- The command *pack* supports customized spec file, refer to https://pyarmor.readthedocs.io/en/latest/advanced. html#bundle-obfuscated-scripts-with-customized-spec-file
- In runtime module *pytransform*, the functions may raise *Exception* instead of *PytransformError* in some cases.
- In command register, add option --legency to store license.lic in the traditional way
- Fix platform name issue: in some linux platforms the platform name may not be right

16.30 5.7.10

• Fix new linux platform *centos6.x86_64* issue: raise TypeError when run *pyarmor* twice.

16.25. 5.8.4

16.31 5.7.9

- Support new linux platform *centos6.x86_64*, arch is x86_64, glibc < 2.14
- Do not print traceback if no option ——debug specified as running pyarmor

16.32 5.7.8

· When the obfuscated scripts raise exception, eliminate the very long line from traceback to make it clear

16.33 5.7.7

• Fix issue: pyarmor load _pytransform.dll faild by 32-bit Python in 64-bit Windows.

16.34 5.7.6

- Add option --update for command download to update all the downloaded dynamic libraries automatically
- Fix issue: the obfuscated script raises unexpected exception when the license is expired

16.35 5.7.5

- Standardize platform names, refer to https://pyarmor.readthedocs.io/en/v5.7.5/platforms.html# standard-platform-names
- Run obfuscated scripts in multiple platforms, refer to https://pyarmor.readthedocs.io/en/v5.7.5/advanced.html# running-obfuscated-scripts-in-multiple-platforms
- Downloaded dynamic library files by command *command* will be saved in the ~/.pyarmor/platforms other than the installed path of pyarmor package.
- Refine *platforms* folder structure according to new standard platform name
- In command *obfuscate*, *build*, *runtime*, specify the option —platform multiple times, so that the obfuscated scripts could run in these platforms

16.36 5.7.4

• Fix issue: command obfuscate fails if the option -- src is specifed

16.37 5.7.3

- Refine pytransform to handle error message of core library
- Refine command online help message
- Sort the scripts being to obfuscated to fix some random errors (#143)

- Raise exception other than call sys.exit if pyarmor is called from another Python script directly
- In the function get_license_info of module pytransform
 - Change the value to None if there is no corresponding information
 - Change the key name expired to upper case EXPIRED

16.38 5.7.2

- Fix plugin codec issue (#138): 'gbk' codec can't decode byte 0x82 in position 590: illegal multibyte sequence
- Project src may be relative path base on project path
- Refine plugin and document it in details: https://pyarmor.readthedocs.io/en/v5.7.2/how-to-do.html# how-to-deal-with-plugins
- Add common option --debug for *pyarmor* to show more information in the console
- Project commands, for examples build, cofig, the last argument supports any valid project configuration file

16.39 5.7.1

- Add command runtime to generate runtime package separately
- · Add the first character as alias for command obfuscate, licenses, pack, init, config, build
- Fix cross platform obfuscating scripts don't work issue (#136). This bug should be exists from v5.6.0 to v5.7.0 Related target platforms *armv5*, *android.aarch64*, *ppc64le*, *ios.arm64*, *freebsd*, *alpine*, *alpine.arm*, *poky-i586*

16.40 5.7.0

There are 2 major changes in this version:

1. The runtime files are saved in the separated folder *pytransform* as package:

```
dist/
  obf_foo.py

pytransform/
  __init__.py
  license.lic
  pytransform.key
  ...
```

Upgrade notes:

- If you have generated new runtime file "license.lic", it should be copied to dist/pytransform other than dist/
- If you'd like to save the runtime files in the same folder with obfuscated scripts as before, obfuscating the scripts with option *package-runtime* like this:

```
pyarmor obfuscate --package-runtime=0 foo.py
pyarmor build --package-runtime=0
```

2. The bootstrap code must be in the obfuscated scripts, and it must be entry script as obfuscating.

16.38. 5.7.2

Upgrade notes:

• If you have inserted bootstrap code into the obfuscated script *dist/foo.py* which is obfuscated but not as entry script manually. Do it by this command after v5.7.0:

```
pyarmor obfuscate --no-runtime --exact foo.py
```

• If you need insert bootstrap code into plain script, first obfuscate an empty script like this:

```
echo "" > pytransform_bootstrap.py
pyarmor obfuscate --no-runtime --exact pytransform_bootstrap.py
```

Then import *pytransform_bootstrap* in the plain script.

Other changes:

- Change default value of project attribute package_runtime from 0 to 1
- Change default value of option --package-runtime from 0 to 1 in command obfuscate
- Add option --no-runtime for command obfuscate
- Add optioin --disable-restrict-mode for command licenses

16.41 5.6.8

- Add option --package-runtime in command obfuscate, config and build
- Add attribute package_runtime for project
- Refine default cross protection code
- Remove deprecated flag for option -- src in command obfuscate
- Fix help message errors in command *obfuscate*

16.42 5.6.7

- Fix issue (#129): "Invalid input packet" on raspberry pi (armv7)
- Add new obfuscation mode: obf code == 2

16.43 5.6.6

· Remove unused exported symbols from core libraries

16.44 5.6.5

- Fix win32 issue: verify license failed in some cases
- · Refine core library to improve security

16.45 5.6.4

• Fix segmentation fault issue for Python 3.8

16.46 5.6.3

• Add option -x in command *licenses* to save extra data in the license file. It's mainly used to extend license type.

16.47 5.6.2

• Fix pyarmor-webui start issue in some cases: can't import name '_project'

16.48 5.6.1

• The command download will check the version of dynamic library to be sure it works with the current PyArmor.

16.49 5.6.0

In this version, new *private capsule*, which use 2048 bits RSA key to improve security for obfucated scripts, is introduced for purchased users. All the trial versions still use one same *public capsule* which use 1024 bits RSA keys. After purchasing PyArmor, a keyfile which includes license key and *private capsule* will be sent to customer by email.

For the previous purchased user, the old private capsules which are generated implicitly by PyArmor after registered PyArmor still work, but maybe not supported later. Contact jondy.zhao@gmail.com if you'd like to use new *private capsule*.

The other changes:

• Command register are refined according to new private capsule

Upgrade Note for Previous Users

There are 2 solutions:

1. Still use old license code.

It's recommanded that you have generated some customized "license.lic" for the obfuscated scrips and these "license.lic" files have been issued to your customers. If use new key file, all the previous "license.lic" does not work, you need generate new one and resend to your customers.

Actually the command *pip install –upgrade pyarmor* does not overwrite the purchased license code, you need not run command *pyarmor register* again. It should still work, you can check it by run *pyarmor -v*.

Or in any machine in which old version pyarmor is running, compress the following 2 files to one archive "pyarmor-regfile.zip":

- license.lic, which locates in the installed path of pyarmor
- .pyarmor_capsule.zip, which locates in the user HOME path

Then register this keyfile in the new version of pyarmor

pyarmor register pyarmor-regfile.zip

16.45. 5.6.4

2. Use new key file.

It's recommanded that you have not yet issued any customized "license.lic" to your customers.

Forward the purchased email received from MyCommerce to jondy.zhao@gmail.com, and the new key file will be sent to the registration email, no fee for this upgrading.

16.50 5.5.7

• Fix webui bug: raise "name 'output' is not defined" as running packer

16.51 5.5.6

- Add new restrict mode 2, 3 and 4 to improve security of the obfuscated scripts, refer to Restrict Mode
- In command obfuscate, option --restrict supports new value 2, 3 and 4
- In command config, option --disable-restrict-mode is deprecrated
- In command *config*, add new option -- restrict
- In command *obfuscate* the last argument could be a directory

16.52 5.5.5

• Win32 issue: the obfuscated scripts will print extra message.

16.53 5.5.4

- Fix issue: the output path isn't correct when building a package with multiple entries
- Fix issue: the obfuscated scripts raise SystemError "unknown opcode" if advanced mode is enabled in some MacOS machines

16.54 5.5.3

 Fix issue: it will raise error "Invalid input packet" to import 2 independent obfuscated packages in 64-bit Windows.

16.55 5.5.2

• Fix bug of command *pack*: the obfuscated modules aren't packed into the bundle if there is an attribute _*code_cache* in the *a.pure*

16.56 5.5.1

- Fix bug: it could not obfuscate more than 32 functions in advanced mode even pyarmor isn't trial version.
- In command *licenses*, the output path of generated license file is truncated if the registration code is too long, and all the invalid characters for path are removed.

16.57 5.5.0

- Fix issue: Warning: code object xxxx isn't wrapped (#59)
- Refine command download, fix some users could not download library file from pyarmor.dashingsoft.com
- Introduce advanced mode for x86/x64 arch, it has some limitations in trial version
- Add option advanced for command obfuscate
- Add new property advanced_mode for project

A new feature **Advanced Mode** is introduced in this version. In this mode the structure of PyCode_Type is changed a little to improve the security. And a hook also is injected into Python interpreter so that the modified code objects could run normally. Besides if some core Python C APIs are changed unexpectedly, the obfuscated scripts in advanced mode won't work. Because this feature is highly depended on the machine instruction set, it's only available for x86/x64 arch now. And pyarmor maybe makes mistake if Python interpreter is compiled by old gcc or some other *C* compiles. It's welcome to report the issue if Python interpreter doesn't work in advanced mode.

Take this into account, the advanced mode is disabled by default. In order to enable it, pass option —advanced to command *obfuscate*. But in next minor version, this mode may be enable by default.

Upgrade Notes:

Before upgrading, please estimate Python interpreter in product environments to be sure it works in advanced mode. Here is the guide

https://github.com/dashingsoft/pyarmor-core/tree/v5.3.0/tests/advanced_mode/README.md

It is recommended to upgrade in the next minor version.

16.58 5.4.6

- Add option --without-license for command pack. Sample usage refer to https://pyarmor.readthedocs.io/en/latest/advanced.html#bundle-obfuscated-scripts-to-one-executable-file
- Add option —debug for command *pack*. If this option isn't set, all the build files will be removed after packing.

16.59 5.4.5

- Enhancement: In Linux support to get the serial number of NVME harddisk
- Fix issue: After run command *register*, pyarmor could not generate capsule if there is *license.lic* in the current path

16.56. 5.5.1

16.60 5.4.4

- Fix issue: In Linux could not get the serial number of SCSI harddisk
- Fix issuse: In Windows the serial number is not right if the leading character is alpha number

16.61 5.4.3

- Add function *get_license_code* in runtime module *pytransform*, which mainly used in plugin to extend license type. Refer to https://pyarmor.readthedocs.io/en/latest/advanced.html#using-plugin-to-extend-license-type
- Fix issue: the command download always shows trial version

16.62 5.4.2

- Option --exclude can use multiple times in command obfuscate
- Exclude build path automatically in command pack

16.63 5.4.1

- New feature: do not obfuscate functions which name starts with lambda_
- Fix issue: it will raise Protection Fault as packing obfuscated scripts to one file

16.64 5.4.0

- Do not obfuscate lambda functions by default
- Fix issue: local variable platname referenced before assignment

16.65 5.3.13

• Add option --url for command download

16.66 5.3.12

• Add integrity checks for the downloaded binaries (#85)

16.67 5.3.11

• Fix issue: get wrong harddisk's serial number for some special cases in Windows

16.68 5.3.10

· Query harddisk's serial number without administrator in Windows

16.69 5.3.9

• Remove the leading and trailing whitespace of harddisk's serial number

16.70 5.3.8

• Fix non-ascii path issue in Windows

16.71 5.3.7

• Fix bug: the bootstrap code isn't inserted correctly if the path of entry script is absolute path.

16.72 5.3.6

- Fix bug: protection code can't find the correct dynamic library if distributing obfuscated scripts to other platforms.
- Document how to distribute obfuscated scripts to other platforms https://pyarmor.readthedocs.io/en/latest/advanced.html#distributing-obfuscated-scripts-to-other-platform

16.73 5.3.5

- The bootstrap code could run many times in same Python interpreter.
- Remove extra. from the bootstrap code of __init__.py as building project without runtime files.

16.74 5.3.4

- Add command download used to download platform-dependent dynamic libraries
- Keep shell line for obfuscated entry scripts if there is first line starts with #!
- Fix issue: if entry script is not in the src path, bootstrap code will not be inserted.

16.75 5.3.3

- · Refine benchmark command
- Document the performance of obfuscated scripts https://pyarmor.readthedocs.io/en/latest/performance.html
- Add command register to take registration code effects

16.68. 5.3.10

• Rename trial license file license.lic to license.tri

16.76 5.3.2

• Fix bug: if there is only one comment line in the script it will raise IndexError as obfuscating this script.

16.77 5.3.1

- Refine pack command, and make output clear.
- Document plugin usage to extend license type for obufscated scripts. Refer to https://pyarmor.readthedocs.io/en/latest/advanced.html#using-plugin-to-extend-license-type

16.78 5.3.0

- In the trial version of PyArmor, it will raise error as obfuscating the code object which size is greater than 32768 bytes.
- Add option --plugin in command *obfuscate*
- Add property *plugins* for Project, and add option --plugin in command *config*
- Change default build path for command pack, and do not remove it after command finished.

16.79 5.2.9

- Fix segmentation fault issue for python3.5 and before: run too big obfuscated code object (>65536 bytes) will crash (#67)
- Fix issue: missing bootstrap code for command pack (#68)
- Fix issue: the output script is same as original script if obfuscating scripts with option --exact

16.80 5.2.8

• Fix issue: pyarmor -v complains not enough arguments for format string

16.81 5.2.7

- In command *obfuscate* add new options --exclude, --exact, --no-bootstrap, --no-cross-protection.
- In command *obfuscate* deprecate the options --src, --entry, --cross-protection.
- In command *licenses* deprecate the option --bind-file.

16.82 5.2.6

- Fix issue: raise codec exception as obfuscating the script of utf-8 with BOM
- Change the default path to user home for command *capsule*
- Disable restrict mode by default as obfuscating special script __init__.py
- · Refine log message

16.83 5.2.5

- Fix issue: raise IndexError if output path is '.' as building project
- For Python3 convert error message from bytes to string as checking license failed
- Refine version information

16.84 5.2.4

- Fix arm64 issue: verify rsa key failed when running the obufscated scripts(#63)
- Support ios (arm64) and ppc64le for linux

16.85 5.2.3

- Refine error message when checking license failed
- Fix issue: protection code raises ImportError in the package file __init.py__

16.86 5.2.2

• Improve the security of dynamic library.

16.87 5.2.1

- Fix issue: in restrict mode the bootstrap code in __init__.py will raise exception.
- Add option --cross-protection in command obfuscate

16.88 5.2.0

- Use global capsule as default capsule for project, other than creating new one for each project
- Add option --obf-code, --obf-mod, --wrap-mode, --cross-protection in command config
- Add new attributes for project: obf_code, obf_mod, wrap_mode, cross_protection
- Deprecrated project attributes obf_code_mode, obf_module_mode, use obf_code, obf_mod, wrap_mode instead

16.82. 5.2.6

- Change the behaviours of restrict mode, refer to https://pyarmor.readthedocs.io/en/latest/advanced.html# restrict-mode
- Change option -- restrict in command obfuscate and licenses
- Remove option --no-restrict in command obfuscate
- Remove option --clone in command init

16.89 5.1.2

• Improve the security of PyArmor self

16.90 5.1.1

- Refine the procedure of encrypt script
- Reform module pytransform.py
- Fix issue: it will raise exception if no entry script when obfuscating scripts
- Fix issue: 'gbk' codec can't decode byte 0xa1 in position 28 (#51)
- Add option --upgrade for command capsule
- Merge runtime files pyshield.key, pyshield.lic and product.key into pytransform.key

Upgrade notes

The capsule created in this version will include a new file *pytransform.key* which is a replacement for 3 old runtime files: *pyshield.key*, *pyshield.lic* and *product.key*.

The old capsule which created in the earlier version still works, it stills use the old runtime files. But it's recommended to upgrade the old capsule to new version. Just run this command:

```
pyarmor capsule --upgrade
```

All the license files generated for obfuscated scripts by old capsule still work, but all the scripts need to be obfuscated again to take new capsule effects.

16.91 5.1.0

- Add extra code to protect dynamic library _pytransform when obfuscating entry script
- Fix compling error when obfuscating scripts in windows for Python 26/30/31 (newline issue)

16.92 5.0.5

• Refine protect_pytransform to improve security, refer to https://pyarmor.readthedocs.io/en/latest/security.html

16.93 5.0.4

- Fix get_expired_days issue, remove decorator dllmethod
- Refine output message of pyarmor -v

16.94 5.0.3

- Add option -q, --silent, suppress all normal output when running any PyArmor command
- Refine runtime error message, make it clear and more helpful
- Add new function get_hd_info in module pytransform to get hardware information
- Remove function get_hd_sn from module pytransform, use get_hd_info instead
- Remove useless function version_info, get_trial_days from module pytransform
- Remove attribute lib_filename from module pytransform, use _pytransform._name instead
- Add document https://pyarmor.readthedocs.io/en/latest/pytransform.html
- Refine document https://pyarmor.readthedocs.io/en/latest/security.html

16.95 5.0.2

 Export lib_filename in the module pytransform in order to protect dynamic library _pytransform. Refer to https://pyarmor.readthedocs.io/en/latest/security.html

16.96 5.0.1

Thanks to GNU lightning, from this version, the core routines are protected by JIT technicals. That is to say, there is no binary code in static file for core routines, they're generated in runtime.

Besides, the pre-built dynamic library for linux arm32/64 are packed into the source package.

Fixed issues:

• The module *multiprocessing* starts new process failed in obfuscated script:

```
AttributeError: '__main__' object has no attribute 'f'
```

16.97 4.6.3

- Fix backslash issue when running pack command with PyInstaller
- When PyArmor fails, if sys.flags.debug is not set, only print error message, no traceback printed

16.93. 5.0.4

16.98 4.6.2

- Add option -- options for command pack
- For Python 3, there is no new line in the output when pack command fails

16.99 4.6.1

• Fix license issue in 64-bit embedded platform

16.100 4.6.0

• Fix crash issue for special code object in Python 3.6

16.101 4.5.5

• Fix stack overflow issue

16.102 4.5.4

• Refine platform name to search dynamic library _pytransform

16.103 4.5.3

• Print the exact message when checking license failed to run obfuscated scripts.

16.104 4.5.2

- Add documentation https://pyarmor.readthedocs.io/en/latest/
- Exclude dist, build folder when executing pyarmor obfuscate –recursive

16.105 4.5.1

• Fix #41: can not find dynamic library _pytransform

16.106 4.5.0

• Add anti-debug code for dynamic library _pytransform

16.107 4.4.2

• Change default capsule to user home other than the source path of pyarmor

16.108 4.4.2

This patch mainly changes webui, make it simple more:

- WebUI: remove source field in tab Obfuscate, and remove ipv4 field in tab Licenses
- WebUI Packer: remove setup script, add output path, only support PyInstaller

16.109 4.4.1

- Support Py2Installer by a simple way
- For command obfuscate, get default src and entry from first argument, --src is not required.
- Set no restrict mode as default for new project and command obfuscate, licenses

16.110 4.4.0

• Pack obfuscated scripts by command pack

In this version, introduces a new command *pack* used to pack obfuscated scripts with *py2exe* and *cx_Freeze*. Once the setup script of *py2exe* or *cx_Freeze* can bundle clear python scripts, *pack* could pack obfuscated scripts by single command: *pyarmor pack_type cx_Freeze /path/to/src/main.py*

· Pack obfuscated scripts by WebUI packer

WebUI is well reformed, simple and easy to use.

http://pyarmor.dashingsoft.com/demo/index.html

16.111 4.3.4

• Fix start pyarmor issue for pip install in Python 2

16.112 4.3.3

• Fix issue: missing file in wheel

16.113 4.3.2

- Fix pip install issue in MacOS
- Refine sample scripts to make workaround for py2exe/cx_Freeze simple

16.107. 4.4.2

16.114 4.3.1

- · Fix typos in examples
- · Fix bugs in sample scripts

16.115 4.3.0

In this version, there are three significant changes:

[Simplified WebUI](http://pyarmor.dashingsoft.com/demo/index.html) [Clear Examples](src/examples/README.md), quickly understand the most features of Pyarmor [Sample Shell Scripts](src/examples), template scripts to obfuscate python source files

- Simply webui, easy to use, only input one filed to obfuscate python scripts
- The runtime files will be always saved in the same path with obfuscated scripts
- Add shell scripts *obfuscate-app*, *obfuscate-pkg*, *build-with-project*, *build-for-2exe* in *src/examples*, so that users can quickly obfuscate their python scripts by these template scripts.
- If entry script is __init__.py, change the first line of bootstrap code from pytransform import pyarmor runtime to from .pytransform import pyarmor runtime
- · Rewrite examples/README.md, make it clear and easy to understand
- Do not generate entry scripts if only runtime files are generated
- Remove choice *package* for option —type in command *init*, only *pkg* reserved.

16.116 4.2.3

- Fix pyarmor-webui can not start issue
- Fix runtime-path issue in webui
- Rename platform name *macosx_intel* to *macosx_x86_64* (#36)

16.117 4.2.2

• Fix webui import error.

16.118 4.2.1

• Add option -- recursive for command obfuscate

16.119 4.1.4

• Rewrite project long description.

16.120 4.1.3

• Fix Python3 issue for get_license_info

16.121 4.1.2

• Add function get_license_info in pytransform.py to show license information

16.122 4.1.1

• Fix import main from pyarmor issue

16.123 4.0.3

- Add command capsule
- Find default capsule in the current path other than --src in command obfuscate
- Fix pip install issue #30

16.124 4.0.2

- Rename pyarmor.py to pyarmor-depreted.py
- Rename pyarmor2.py to pyarmor.py
- Add option --capsule, -disable-restrict-mode and --output for command licenses

16.125 4.0.1

- Add option -- capsule for command init, config and obfuscate
- Deprecate option --clone for command init, use --capsule instead
- Fix sys.settrace and sys.setprofile issues for auto-wrap mode

16.126 3.9.9

• Fix segmentation fault issues for asyncio, typing modules

16.127 3.9.8

• Add documentation for examples (examples/README.md)

16.120. 4.1.3

16.128 3.9.7

• Fix windows 10 issue: access violation reading 0x000001ED00000000

16.129 3.9.6

- Fix the generated license bind to fixed machine in webui is not correct
- Fix extra output path issue in webui

16.130 3.9.5

• Show registration code when printing version information

16.131 3.9.4

· Rewrite long description of package in pypi

16.132 3.9.3

• Fix issue: __file__ is not really path in main code of module when import obfuscated module

16.133 3.9.2

- Replace option --disable-restrict-mode with --no-restrict in command obfuscate
- Add option --title in command config
- Change the output path of entry scripts when entry scripts belong to package
- Refine document user-guide.md and mechanism.md

16.134 3.9.1

- Add option -- type for command init
- Refine document user-guide.md and mechanism.md

16.135 3.9.0

This version introduces a new way *auto-wrap* to protect python code when it's imported by outer scripts. Refer to [Mechanism Without Restrict Mode](src/mechanism.md#mechanism-without-restrict-mode)

• Add new mode wrap for --obf-code-mode

- Remove func.__refcalls__ in __wraparmor__
- Add new project attribute is_package
- Add option --is-package in command config
- Add option --disable-restrict-mode in command obfuscate
- Reset build time when project configuration is changed
- Change output path when is_package is set in command build
- Change default value of project when find __init__.py in comand init
- Project attribute *entry* supports absolute path

16.136 3.8.10

• Fix shared code object issue in __wraparmor__

16.137 3.8.9

- Clear frame as long as tb is not Py_None when call __wraparmor__
- Generator will not be obfucated in __wraparmor__

16.138 3.8.8

• Fix bug: the *frame.f_locals* still can be accessed in callback function

16.139 3.8.7

• The *frame.f_locals* of *wrapper* and wrapped function will return an empty dictionary once *__wraparmor__* is called.

16.140 3.8.6

• The *frame.f_locals* of *wrapper* and wrapped function return an empty dictionary, all the other frames still return original value.

16.141 3.8.5

- The frame.f_locals of all frames will always return an empty dictionary to protect runtime data.
- Add extra argument tb when call <u>_wraparmor</u> in decorator wraparmor, pass None if no exception.

16.136. 3.8.10

16.142 3.8.4

• Do not touch frame.f_locals when raise exception, let decorator wraparmor to control everything.

16.143 3.8.3

- Fix issue: option --disable-restrict-mode doesn't work in command licenses
- Remove freevar func from frame.f_locals when raise exception in decorator wraparmor

16.144 3.8.2

• Change module filename to < frozen modname > in traceback, set attribute __file__ to real filename when running obfuscated scripts.

16.145 3.8.1

• Try to access original func_code out of decorator wraparmor is forbidden.

16.146 3.8.0

- Add option -- output for command build, it will override the value in project configuration file.
- Fix issue: defalut project output path isn't relative to project path.
- Remove extra file "product.key" after obfuscating scripts.

16.147 3.7.5

• Remove dotted name from filename in traceback, if it's not a package.

16.148 3.7.4

• Strip __init__ from filename in traceback, replace it with package name.

16.149 3.7.3

• Remove brackets from filename in traceback, and add dotted prefix.

16.150 3.7.2

• Change filename in traceback to <frozen [modname]>, other than original filename

16.151 3.7.1

- Fix issue #12: module attribute __file__ is filename in build machine other than filename in target machine.
- Builtins function __wraparmor__ only can be used in the decorator wraparmor

16.152 3.7.0

- Fix issue #11: use decorator "wraparmor" to obfuscate func_code as soon as function returns.
- Document usage of decorator "wraparmor", refer to src/user-guide.md#use-decorator-to-protect-codeobjects-when-disable-restrict-mode

16.153 3.6.2

• Fix issue #8 (Linux): option –manifest broken in shell script

16.154 3.6.1

- Add option "Restrict Mode" in web ui
- Document restrict mode in details (user-guide.md)

16.155 3.6.0

- Introduce restrict mode to avoid obfuscated scripts observed from no obfuscated scripts
- Add option –disable-restrict-mode for command "config"

16.156 3.5.1

• Support pip install pyarmor

16.157 3.5.0

- Fix Python3.6 issue: can not run obfuscated scripts, because it uses a 16-bit wordcode instead of bytecode
- Fix Python3.7 issue: it adds a flag in pyc header
- Fix option -obf-module-mode=none failed
- Add option -clone for command "init"
- Generate runtime files to separate path "runtimes" when project runtime-path is set
- Add advanced usages in user-guide

16.151. 3.7.1

16.158 3.4.3

• Fix issue: raise exception when project entry isn't obfuscated

16.159 3.4.2

· Add webui to manage project

16.160 3.4.1

- Fix README.rst format error.
- Add title attribute to project
- Print new command help when option is -h, -help

16.161 3.4.0

Pyarmor v3.4 introduces a group new commands. For a simple package, use command **obfuscate** to obfuscate scripts directly. For complicated package, use Project to manage obfuscated scripts.

Project includes 2 files, one configure file and one project capsule. Use manifest template string, same as MANI-FEST.in of Python Distutils, to specify the files to be obfuscated.

To create a project, use command **init**, use command **info** to show project information. **config** to update project settings, and **build** to obfuscate the scripts in the project.

Other commands, **benchmark** to metric performance, **hdinfo** to show hardware information, so that command **licenses** can generate license bind to fixed machine.

All the old commands **capsule**, **encrypt**, **license** are deprecated, and will be removed from v4.

A new document src/user-guide.md is written for this new version.

16.162 3.3.1

· Remove unused files in distribute package

16.163 3.3.0

In this version, new obfuscate mode 7 and 8 are introduced. The main difference is that obfuscated script now is a normal python file (.py) other than compiled script (.pyc), so it can be used as common way.

Refer to https://github.com/dashingsoft/pyarmor/blob/v3.3.0/src/mechanism.md

- Introduce new mode: 7, 8
- Change default mode from 3 to 8
- Change benchmark.py to test new mode

- · Update webapp and tutorial
- · Update usage
- Fix issue of py2exe, now py2exe can work with python scripts obfuscated by pyarmor
- Fix issue of odoo, now odoo can load python modules obfuscated by pyarmor

16.164 3.2.1

- Fix issue: the traceback of an exception contains the name "<pytransform>" instead of the correct module name
- Fix issue: All the constant, co_names include function name, variable name etc still are in clear text. Refer to https://github.com/dashingsoft/pyarmor/issues/5

16.165 3.2.0

From this version, a new obfuscation mode is introduced. By this way, no import hooker, no setprofile, no settrace required. The performance of running or importing obfuscation python scripts has been remarkably improved. It's significant for Pyarmor.

- Use this new mode as default way to obfuscate python scripts.
- Add new script "benchmark.py" to check performance in target machine: python benchmark.py
- Change option "-bind-disk" in command "license", now it must be have a value

16.166 3.1.7

- Add option "-bind-mac", "-bind-ip", "-bind-domain" for command "license"
- Command "hdinfo" show more information(serial number of hdd, mac address, ip address, domain name)
- Fix the issue of dev name of hdd for Banana Pi

16.167 3.1.6

• Fix serial number of harddisk doesn't work in mac osx.

16.168 3.1.5

· Support MACOS

16.169 3.1.4

- Fix issue: load _pytransfrom failed in linux x86_64 by subprocess.Popen
- Fix typo in error messge when load _pytransfrom failed.

16.164. 3.2.1

16.170 3.1.3

A web gui interface is introduced as Pyarmor WebApp and support MANIFEST.in

- In encrypt command, save encrypted scripts with same file structure of source.
- Add a web gui interface for pyarmor.
- Support MANIFEST.in to list files for command encrypt
- Add option -manifest, file list will be written here
- DO NOT support absolute path in file list for command encrypt
- Option –main support format "NAME:ALIAS.py"

16.171 3.1.2

- Refine decrypted mechanism to improve performance
- Fix unknown opcode problem in recursion call
- Fix wrapper scripts generated by -m in command 'encrypt' doesn't work
- Raise ImportError other than PytransformError when import encrypted module failed

16.172 3.1.1

In this version, introduce 2 extra encrypt modes to improve performance of encrypted scripts.

- Fix issue when import encrypted package
- Add encrypted mode 2 and 3 to improve performance
- Refine module pyimcore to improve performance

16.173 3.0.1

It's a milestone for Pyarmor, from this version, use ctypes import dynamic library of core functions, other than by python extensions which need to be built with every python version.

Besides, in this version, a big change which make Pyarmor could avoid soure script got by c debugger.

- Use ctypes load core library other than python extentions which need built for each python version.
- "__main__" block not running in encrypted script.
- Avoid source code got by c debugger.
- Change default outoupt path to "build" in command "encrypt"
- Change option "-bind" to "-bind-disk" in command "license"
- Document usages in details

16.174 2.6.1

• Fix encrypted scripts don't work in multi-thread framework (Django).

16.175 2.5.5

· Add option '-i' for command 'encrypt' so that the encrypted scripts will be saved in the original path.

16.176 2.5.4

- Verbose tracelog when checking license in trace mode.
- In license command, change default output filename to "license.lic.txt".
- Read bind file when generate license in binary mode other than text mode.

16.177 2.5.3

- Fix problem when script has line "from __future__ import with_statement"
- Fix error when running pyarmor by 32bit python on the 64bits Windows.
- (Experimental)Support darwin_15-x86_64 platform by adding extensions/pytransform-2.3.3.darwin_15.x86_64-py2.7.so

16.178 2.5.2

- License file can mix expire-date with fix file or fix key.
- Fix log error: not enough arguments for format string

16.179 2.5.1

• License file can bind to ssh private key file or any other fixed file.

16.180 2.4.1

- Change default extension ".pyx" to ".pye", because it confilted with CPython.
- Custom the extension of encrypted scripts by os environment variable: PYARMOR_EXTRA_CHAR
- Block the hole by which to get bytescode of functions.

16.174. 2.6.1

16.181 2.3.4

• The trial license will never be expired (But in trial version, the key used to encrypt scripts is fixed).

16.182 2.3.3

• Refine the document

16.183 2.3.2

• Fix error data in examples of wizard

16.184 2.3.1

- Implement Run function in the GUI wizard
- Make license works in trial version

16.185 2.2.1

- · Add a GUI wizard
- Add examples to show how to use pyarmor

16.186 2.1.2

• Fix syntax-error when run/import encrypted scripts in linux x86_64

16.187 2.1.1

• Support armv6

16.188 2.0.1

- Add option '-path' for command 'encrypt'
- Support script list in the file for command 'encrypt'
- Fix issue to encrypt an empty file result in pytransform crash

16.189 1.7.7

- · Add option '-expired-date' for command 'license'
- Fix undefined 'tfm_desc' for arm-linux
- Enhance security level of scripts

16.190 1.7.6

- Print exactaly message when pyarmor couldn't load extension "pytransform"
- Fix problem "version 'GLIBC_2.14' not found"
- Generate "license.lic" which could be bind to fixed machine.

16.191 1.7.5

• Add missing extensions for linux x86_64.

16.192 1.7.4

• Add command "licene" to generate more "license.lic" by project capsule.

16.193 1.7.3

• Add information for using registration code

16.194 1.7.2

- Add option –with-extension to support cross-platform publish.
- Implement command "capsule" and add option –with-capsule so that we can encrypt scripts with same capsule.
- Remove command "convert" and option "-K/-key"

16.195 1.7.1

• Encrypt pyshield.lic when distributing source code.

16.189. 1.7.7

16.196 1.7.0

- Enhance encrypt algorithm to protect source code.
- Developer can use custom key/iv to encrypt source code
- Compiled scripts (.pyc, .pyo) could be encrypted by pyshield
- Extension modules (.dll, .so, .pyd) could be encrypted by pyshield
